Dirac Lagrangian U (1) Gauge Symmetry

So, we discussed the Lagrangian and how to get the equations of motion from that a Lagrangian in particular we considered the Lagrangian, Lagrangians of fields that will give us the equations of motion corresponding to a Fermionic particle which is basically the Dirac equation.

And similarly for the Klein Gordon equation we had written down the Lagrangian and also for the Lagrangian that would give us the Maxwell's equation, what we studied was the free particle. Now if you want to now look at interactions from the same framework or in the same framework, then how do we actually take that into account this what we will discuss today.

(Refer Slide Time: 01:43)

Dirac Lagrangian

$$\mathcal{L} = i \bar{\psi} \gamma^\mu \partial_\mu \psi - m \bar{\psi} \psi$$
$$\psi \rightarrow \psi' = e^{i\alpha} \psi, \quad \alpha: \text{constant}$$
$$\bar{\psi} \rightarrow \bar{\psi}' = \bar{\psi} e^{-i\alpha}$$
$$\partial_\mu \psi \rightarrow \partial_\mu \psi' = \partial_\mu (e^{i\alpha} \psi) = e^{i\alpha} \partial_\mu \psi$$
$$\mathcal{L} \rightarrow \mathcal{L}' = i \bar{\psi}' \gamma^\mu \partial_\mu \psi' - m \bar{\psi}' \psi'$$
$$= i \bar{\psi} \gamma^\mu \partial_\mu \psi - m \bar{\psi} \psi = \mathcal{L}$$

Let us consider the Dirac Lagrangian, by which I mean the Lagrangian that will give us the Dirac equation $i \bar{\psi} \gamma^\mu \partial_\mu \psi - m \bar{\psi} \psi$. We saw yesterday that this indeed leads to the Dirac equation for the wave function or ψ or for the field ψ . Now consider a transformation of ψ which goes to some ψ'

which is equal to some exponential $i\alpha$ times ψ where α is some constant some kind of a phase factor which we add to ψ , $\bar{\psi}$ will go then $e^{-i\alpha}$ $\bar{\psi}$ and the other element then the Lagrangian is derivative of ψ derivative of $\bar{\psi}$ will go to derivative of $\bar{\psi}$ ψ' .

We are not changing the transforming the space time coordinates at all, we are in the same space time coordinate we could even be in the same reference frame and changing only the form of the wave the field ψ . So, this will now be derivative acting on the new field transformed field with all field with the exponential $i\alpha$ pre multiplying it.

The first factor exponential $i\alpha$ is independent of space time coordinates because α we have taken as a constant. So, that will not be affected by this and then we have essentially $e^{i\alpha}$ $\partial_\mu \psi$. Let us put all these back in the Lagrangian so, Lagrangian will go to some L' say is $i\bar{\psi}' \gamma_\mu \psi$, there is no change $\partial_\mu \psi$ ψ' minus $m \bar{\psi} \psi$ when I multiply $\bar{\psi}$ and ψ together exponential terms cancel exponential factors cancelled.

Similarly the since $\bar{\psi}'$ has $e^{-i\alpha}$ and $\partial_\mu \psi'$ also has a $i\alpha$ similar to ψ' with the same exponential factor exponential $i\alpha$, it actually cancels with each other. So, all together you will get back the original equation $m \bar{\psi}$ was registered an in ψ' in the earlier equation here it is which is equal to L .

So, we see that the Lagrangian that we have written down in the first line is invariant under the transformation of ψ go into ψ' equal to exponential $i\alpha$ ψ with α a constant this transformation is called a gauge transformation a global gauge transformation.

(Refer Slide Time: 05:36)

$$\begin{aligned}
& \mathcal{L} \text{ is invariant under} \\
& \text{the global gauge transformation, } \psi \rightarrow e^{i\alpha} \psi \\
& e^{i\alpha} \in U(1) \text{ group (Unitary group)} \\
\hline
& \text{A set:} \quad (i) \text{ identity element : } \alpha=0 \Rightarrow e^{i\alpha}=1 \\
& \quad (ii) \text{ inverse element : } e^{i\alpha} \in U(1) \\
& \quad \quad \quad e^{-i\alpha} \in U(1) \Rightarrow e^{i\alpha} \cdot e^{-i\alpha} = 1 \\
& \quad (iii) \quad e^{i\alpha}, e^{i\beta} \in U(1) \Rightarrow e^{i\alpha} \cdot e^{i\beta} = e^{i(\alpha+\beta)} \in U(1) \\
& \quad (iv) \quad e^{i\alpha} (e^{i\beta} \cdot e^{i\gamma}) = (e^{i\alpha} \cdot e^{i\beta}) \cdot e^{i\gamma}
\end{aligned}$$

So, what we see is that \mathcal{L} is invariant under the let me call it global gauge transformation which actually says that ψ goes to exponential $i\alpha\psi$. So, this is the standard terminology global gauge transformation.

Now, take $e^{i\alpha}$ if you know group theory you will recognize that this is an element of $U(1)$ group if you do not know what is the meaning of a group, let us just briefly tell you what it is the a set you take any set that satisfy the following properties you take there should be an identity element in that.

In our case if you put $\alpha=0$ that will give you $e^{i\alpha}=1$ and you multiply anything by one will give you the same thing for example, it is an identity transformation when you take ψ to ψ itself. So, for $\alpha=0$ this ψ will go to ψ it should have an inverse transformation. So, for group theory there is an inverse element, which means that if $e^{i\alpha}$ is an element of $U(1)$, then $e^{-i\alpha}$ is also an element of $U(1)$. So, that $e^{i\alpha} \cdot e^{-i\alpha}$ is equal to unity the identity.

So, for every element there is another element when you multiply them together and that when you take them together you will get unity or identity, then other thing is that if $e^{i\alpha}$ and $e^{i\beta}$ are 2 elements of $U(1)$, in this case we are actually illustrating the group property by $U(1)$, but you can this is applicable to any group. If these were 2 elements of the group which are considering you take any 2 elements which are which are I mean 2 elements of the concerned group.

Then a combination of that product of that $e^{\alpha} e^{\beta}$ is equal to $e^{\alpha + \beta}$ is also an element of $U(1)$. So, the set is such that if you have 2 elements I mean when you consider 2 elements and then multiply them, then you will get another element of the group the product of 2 elements will be an element of the group.

This is the closure property is called the closure property when I say here multiplication in this case in this particular case it is actually the multiplication, but in general for any group it need not always be multiplication it is either multiplication or any other group operation whatever is the group operation.

So, along with the set you had to also define, what is the group operation? So, then you will see that all these things are satisfied when you combine these 2 elements which means that you are doing the group operation between these 2 elements. Such combination is associative which means if I take 3 elements $e^{\alpha} e^{\beta} e^{\gamma}$, it does not matter whether I club 2 of them first any the last 2 of them first and then multiply combined that resultant element with the first one or take the first 2 and combine them to give a resultant element and then combine that with the third this is the group associative property of the group elements.

So, any set that satisfy these condition these conditions are called is called a group in this particular case $U(1)$ can take continuous values any value and then therefore, it is called it is a continuous group $U(1)$ is a continuous group U actually means unitary. So, it is a unitary group and there is only one parameter to represent the group element. So, that is why you have 1 in the bracket $U(1)$ and then bracket 1.

So, we will not go into any further details of group theory, we will advise you to go through any elementary book on group theory to familiarize yourself with the properties of group theory and algebra group theory etcetera especially the one which is of our interest is called is the a continuous group or are continuous groups are what we are interested in and the these groups are called Li groups.

(Refer Slide Time: 12:32)

$$\begin{aligned}
\mathcal{L} &= i \bar{\psi} \gamma^\mu \partial_\mu \psi - m \bar{\psi} \psi \\
\psi &\rightarrow \psi' = e^{i\alpha(x)} \psi \\
\bar{\psi} &\rightarrow \bar{\psi}' = e^{-i\alpha(x)} \bar{\psi}
\end{aligned}
\left. \vphantom{\begin{aligned} \psi &\rightarrow \psi' \\ \bar{\psi} &\rightarrow \bar{\psi}' \end{aligned}} \right\} \text{Local gauge transformation}$$

$$\begin{aligned}
\partial_\mu \psi &\rightarrow \partial_\mu \psi' = \partial_\mu (e^{i\alpha} \psi) \\
&= i(\partial_\mu \alpha) e^{i\alpha} \psi + e^{i\alpha} \partial_\mu \psi \\
&= e^{i\alpha} (\partial_\mu \psi + i(\partial_\mu \alpha) \psi)
\end{aligned}$$

Now, let us come back to the transformation of the Lagrangian the Dirac Lagrangian, let me write that again $i \bar{\psi} \gamma^\mu \partial_\mu \psi - m \bar{\psi} \psi$, let us again consider a transformation ψ goes to ψ' which is equal to $e^{i\alpha} \psi$. Difference is a difference with the earlier transformation is that we are now not considering α a constant, but a function of space time coordinate x , I will not write the index μ on the space time the x there because it becomes too clumsy for us..

So, when I say α is a function of space time coordinate, what about $\bar{\psi}$, $\bar{\psi}$ will also transform similar way $e^{-i\alpha} \bar{\psi}$, no problem. Let us look at derivative of ψ it is derivative of ψ' now which is equal to derivative acting on $e^{i\alpha} \psi$ I will not write the x dependence explicitly it is understood.

But now since α is not a constant, but a function of the space time coordinates the derivative will act on the exponential the factor. So, it is i times derivative with the derivative of α times same thing $e^{i\alpha} \psi$ plus $e^{i\alpha} \partial_\mu \psi$, where I can write this as $e^{i\alpha} (\partial_\mu \psi + i(\partial_\mu \alpha) \psi)$. So, there is an additional term in this one now coming up.

(Refer Slide Time: 14:58)

$$\begin{aligned}
\mathcal{L}' &= i \bar{\psi}' \gamma^\mu (\partial_\mu \psi') - m \bar{\psi}' \psi' \\
&= i \bar{\psi} e^{-i\alpha} \gamma^\mu e^{i\alpha} (\partial_\mu \psi + i(\partial_\mu \alpha) \psi) - m \bar{\psi} \psi \\
&= \underbrace{i \bar{\psi} \gamma^\mu \partial_\mu \psi - m \bar{\psi} \psi}_{\mathcal{L}} - [(\partial_\mu \alpha) \cdot \bar{\psi} \gamma^\mu \psi] = \mathcal{L}
\end{aligned}$$

\mathcal{L} is not invariant under local gauge $U(1)$
 $\psi \rightarrow \psi' = e^{i\alpha(x)} \psi$

So, what happens to that in the Lagrangian, you have now $i \bar{\psi}' \gamma^\mu \partial_\mu \psi'$. So, this is your, i prime minus m $\bar{\psi}' \psi'$, second term is invariant under this transformation because the phase factors cancel with each other the first term the phase factors cancel with each other, but there is an additional term. So, $\bar{\psi}' \psi'$ is $e^{-i\alpha} \bar{\psi} e^{i\alpha} \psi$ then you have the $\gamma^\mu \partial_\mu \psi + i(\partial_\mu \alpha) \psi$, we have multiplied by $\bar{\psi}$ minus $m \bar{\psi} \psi$ I think in this expression I miss this ψ here should be there in.

The exponential factors indeed cancel, but problem is that in addition to the original Lagrangian which is these 2 terms you have a term which is basically you have a i there and i here. So, it is $-(\partial_\mu \alpha) \bar{\psi} \gamma^\mu \psi$. So, there is an additional term which is which means the Lagrangian different from the original one question is then also this particular this Lagrangian is not invariant under the transformation.

So, this transformation is basically called the this transformation is called local gauge transformation it is called local because α depends on the local points the point at which you are talking about it is not globally defined it is not defined for all the points it is a different it can be can have one value at x_1 and it can have another value at x_2 . So, this is a local locally defined quantity different points will have α differing from each other. So, \mathcal{L} is not invariant under local gauge transformation \mathcal{L} as we have to written it is

not invariant under the local gauge transformation ψ goes to $\psi' = e^{i\alpha} \psi$.

Now, supposing we say that where I want the say Lagrangians may not be this particular Lagrangians, but I want to have a modified Lagrangian, but I want the local gauge symmetry for that Lagrangian I insist on that what will happen in that case. So, what we are to do is. So, find a way to cancel this additional term here. So, this term which I have underlined by this red color.

In addition in is an additional term in the new Lagrangian compared to the old one. So, somehow we have to arrange things. So, that this is canceled when you go from L to L' . So, the Lagrangian has to be modified we also recognize that this is a μ α is actually a vector quantity. So, there is a vector quantity that has to be that is going to these pre multiplying a current like quantity here. The whole issue was with the derivative term you see that the derivative is not of the same form as same the transformations of derivative.

The transformations of ψ is this way $\bar{\psi}$ transform in a similar way, but look at $\mu \psi$, $\mu \psi$ does not transform in a similar way the object that you have in the on the left hand side and the form of the object that you have on the right hand side are completely different that is because of that additional term the second term in this bracket here.

Otherwise it should have been fine like in the global case that is what we had in the global case we had this and this transforming in a very similar way. So, this is the same as what you have the same natures what you have on the left hand side and left hand side right hand side and the left hand side. Now how do you make this derivative in a in the same fashion is what we want to understand.

(Refer Slide Time: 21:09)

$$\begin{aligned}
D_\mu &\equiv \partial_\mu + e A_\mu \rightarrow \partial_\mu + e A'_\mu \\
D_\mu \psi &\rightarrow D'_\mu \psi' = (\partial_\mu + e A'_\mu) (e^{i\alpha} \psi) \\
&= \partial_\mu (e^{i\alpha} \psi) + e A'_\mu \cdot e^{i\alpha} \psi \\
&= e^{i\alpha} (\partial_\mu \psi + i(\partial_\mu \alpha) \psi + e A'_\mu \psi) \\
A'_\mu &= A_\mu + \delta A_\mu \Rightarrow D'_\mu \psi' = e^{i\alpha} [\partial_\mu \psi + i(\partial_\mu \alpha) \psi + e A_\mu \psi + e \delta A_\mu \psi]
\end{aligned}$$

For that we define a new kind of derivative which is equal to or defined as the ordinary derivative plus $e A$ vector quantity μ , this has to be a vector because the first term is A vector. So, what we have in the second term should be A vector of course, we denote that by a μ whatever that vector is some vector field is handed multiplying this adding to the $\partial_\mu \psi$ you to give a new kind of derivative and now what happens to the $\mu \psi$.

So, $D_\mu \psi$ will go to $D'_\mu \psi'$ which is equal to $D_\mu \psi$ or let me expand the $D_\mu \psi$ $\partial_\mu \psi + e A_\mu \psi$ and $\psi' = e^{i\alpha} \psi$ and $e^{i\alpha}$ ψ , let me expand this first is the derivative acting on $e^{i\alpha} \psi$ which we know are true what is the result. Second is $e A_\mu e^{i\alpha} \psi$ so, altogether I have $e^{i\alpha}$ from the expression from the expression here that if or $i \partial_\mu \alpha \psi + i \partial_\mu \alpha \psi$.

So, that is what I will write down first $\partial_\mu \psi + i \partial_\mu \alpha \psi$ then you have another term plus $e A_\mu$, but now let us say along with the transformation of ψ I also want ψ' to be changed. So, it is not just the D , but a D' $\partial_\mu \psi'$ the first factor in D is not going to be changed. So, this will go to $\partial_\mu \psi + e A_\mu \psi$ so, it is $e A_\mu \psi$ that you have here. So, A_μ is what you have here and that is it ψ' of course.

Now, if I take A_μ as the original one plus some δA_μ , then that will give you $D'_\mu \psi'$ is equal to $e^{i\alpha}$ first term as it is, second term as it is, the other term is $e A_\mu \psi + e \delta A_\mu \psi$. So, in this so, let me take that the

combine the terms first let me take the first term and third, first term and third term when you combine what you get is following.

(Refer Slide Time: 25:26)

$$\begin{aligned}
 D'_\mu \psi' &= e^{i\alpha} (\partial_\mu \psi + e A_\mu \psi) \\
 &\quad + e^{i\alpha} (i \partial_\mu \alpha) \psi + e^{i\alpha} (e \delta A_\mu) \psi \\
 &= e^{i\alpha} \underline{D_\mu \psi} + e^{i\alpha} e (\delta A_\mu + \frac{i}{e} \partial_\mu \alpha) \psi \\
 \Rightarrow \delta A_\mu &= -\frac{i}{e} \partial_\mu \alpha \\
 \Rightarrow A'_\mu &= A_\mu - \frac{i}{e} \partial_\mu \alpha.
 \end{aligned}$$

So, $D_\mu \psi'$ is equal to $e^{i\alpha} (\partial_\mu \psi + e A_\mu \psi)$, then you have $e^{i\alpha} (i \partial_\mu \alpha) \psi + e^{i\alpha} (e \delta A_\mu) \psi$.

First align the first term 2 terms is essentially $D_\mu \psi$ then you have additional 2 terms. So, what you have to do is to make these 2 terms cancel each other so, that is all you had to do. So, this is $e^{i\alpha}$ let me take e also outside then that will give you $\delta A_\mu + \frac{i}{e} \partial_\mu \alpha$.

So, if for this to cancel you have to have δA_μ equal to $-\frac{i}{e} \partial_\mu \alpha$. So, that will tell you that A'_μ is equal to $A_\mu - \frac{i}{e} \partial_\mu \alpha$. So, essentially what we are saying so, this is clear what we are trying to say is that for the Lagrangian to be invariant under the (Refer Time: 28:08) transformation what we want is only the first term here the other the rest of it should vanish so, that is what we wanted.

And for that we can actually make δA_μ equal to opposite of the second term in that bracket then it will vanish. So, that is what we have here that is, what is leading to A'_μ equal to $A_\mu - \frac{i}{e} \partial_\mu \alpha$ very good.

(Refer Slide Time: 28:45)

$$\mathcal{L} = i\bar{\psi}\gamma^\mu D_\mu\psi - m\bar{\psi}\psi$$

$$D_\mu = \partial_\mu + eA_\mu$$

\mathcal{L} is invariant under:

$$\psi \rightarrow \psi' = e^{i\alpha(x)}\psi$$

$$A_\mu \rightarrow A'_\mu = A_\mu - \frac{1}{e}\partial_\mu\alpha$$

So, what we have is the following Lagrangian $i\bar{\psi}\gamma^\mu D_\mu\psi - m\bar{\psi}\psi$ with D_μ defined as $\partial_\mu + eA_\mu$ is invariant under the transformation ψ going to $\psi' = e^{i\alpha(x)}\psi$ and A_μ going to $A'_\mu = A_\mu - \frac{1}{e}\partial_\mu\alpha$.

Together they make sure that the Lagrangian that is written down is invariant under these transform 2 transformations. So, we have a way out of this we have a Lagrangian new Lagrangian now. So, we have a new Lagrangian now, which has an additional term compared to the old one be considered, but; that means, the new Lagrangian invariant and along with the transformation of ψ we had to also consideration consider a transformation of A_μ at the new fields. So, together they are called the gauge local gauge transformation of A and ψ all right so, this is what we have achieved that is very good.

(Refer Slide Time: 31:13)

$$\begin{aligned}
\mathcal{L} &= i\bar{\psi}\gamma^\mu(\partial_\mu\psi) + i\bar{\psi}\gamma^\mu(eA_\mu)\psi - m\bar{\psi}\psi \\
\frac{\partial\mathcal{L}}{\partial\bar{\psi}} &= i\gamma^\mu\partial_\mu\psi + i\gamma^\mu eA_\mu\psi - m\psi \\
\text{Eq. of motion: } & [i\gamma^\mu\partial_\mu\psi - m\psi] + i\gamma^\mu eA_\mu\psi = 0 \\
i\partial_\mu &\rightarrow i\partial_\mu + eA_\mu
\end{aligned}$$

And now let us look at the equations of motion of psi bar with this. So, L is equal to i psi bar gamma mu dou mu psi plus i psi bar gamma mu e A mu psi minus m psi bar psi. So, this now will give you dou L by dou psi bar equal to i gamma mu dou mu psi plus i gamma mu e A mu psi minus m psi.

This is equal to 0 is your equation of motion because there is no derivative term of psi bar. So, this gives us equation of motion of psi as i gamma mu dou mu psi minus m psi recognized this as the free a particle free Dirac equation corresponding to a free particle determined I mean described by psi then there is an additional term plus i gamma mu e A mu psi equal to 0.

So, to interpret everything correctly now this looks like an interaction term, that we had written down earlier where we said that if I change the momentum from a free particle to any new free particle to interacting particle what I had to do is to change the momentum from i dou mu to i dou mu plus e A mu this is what I had to do to introduce the electromagnetic interactions, to accommodate these we had to actually main the gauge transformation change there is an extra i factor here the way we had done the transformation, but this can be taken care by considering dou mu is equal to dou mu i e A mu.

(Refer Slide Time: 34:02)

$$\begin{aligned}
D_\mu &= \partial_\mu - ieA_\mu \\
\Rightarrow (-iA'_\mu) &= (-iA_\mu) - \frac{i}{e}(\partial_\mu \alpha) \\
A'_\mu &= A_\mu + \frac{1}{e}(\partial_\mu \alpha) \\
\Rightarrow \mathcal{L} &= \left[i\bar{\psi}\gamma^\mu\partial_\mu\psi - m\bar{\psi}\psi \right] + \underbrace{\bar{\psi}\gamma^\mu\psi eA_\mu}
\end{aligned}$$

So, if I consider that then what we have. So, this is what the transformation that we will consider which means that I have multiplied eA by A minus i . So, that will give me everything should be alright, excepting that the transformation of A now is A prime is equal to. So, basically $-iA$ prime will transform as $-iA_\mu - \frac{i}{e}\partial_\mu\alpha$ or I can say that A_μ transforms as A_μ prime equal to $A_\mu + \frac{1}{e}\partial_\mu\alpha$.

So, this is the new A and with this the Lagrangian is equal to $i\bar{\psi}\gamma^\mu\partial_\mu\psi - m\bar{\psi}\psi + \bar{\psi}\gamma^\mu\psi eA_\mu$ and indeed this is of the form that we had earlier for an electron or an charged particle represented by ψ interacting with the electromagnetic field represented by A_μ .

So, essentially what we have achieved by insisting on the Lagrangian to be invariant under the gauge transformation is that we have today we are then forced to introduce electromagnetic interaction of the particles in this thing, turning around we can say that interaction of the particle can be understood through the gauge transformations or the gauge symmetry of the Lagrangian.

This A_μ that we have introduced A appears in the Lagrangian only in the interaction term only in the interaction term here see, but if you want to interpret this as a particle like a photon then of course, you have to also have to tell about what happens to the free part of the photon and how does it propagate, what is the equation of motion

corresponding to the photon or even if you consider it as electromagnetic field you have to also get the Maxwell's equation out of this thing.

(Refer Slide Time: 37:49)

$$\mathcal{L} = \left[\bar{\psi} i \gamma^\mu \partial_\mu \psi - m \bar{\psi} \psi \right] + e \bar{\psi} \gamma^\mu \psi A_\mu - \frac{1}{4} F_{\mu\nu} F^{\mu\nu}$$

$$j^\mu = -e \bar{\psi} \gamma^\mu \psi$$

$$\mathcal{L} = \left[\bar{\psi} i \gamma^\mu \partial_\mu \psi - m \bar{\psi} \psi \right] + \left\{ -\frac{1}{4} F_{\mu\nu} F^{\mu\nu} - j^\mu A_\mu \right\}$$

Quantum Electrodynamics (QED)

So, to do that what then we have to do is, to introduce the another term which will give you the rest of the Maxwell's equation with this. So, psi bar gamma mu dou mu psi minus m psi bar psi plus e psi bar gamma mu psi A mu is what I have I add 1 over 4 F mu u F mu u with this.

Now, look at the last 2 terms the last 2 terms if I consider J mu to be minus e psi bar gamma mu psi then L is psi bar I gamma mu dou mu psi minus m psi bar psi the free part of the Dirac Lagrangian plus I have one part minus 1 over 4 F mu u F mu u minus J mu A mu.

This is precisely that the, what is there in the curly bracket is precisely the Lagrangian that we used to get the Maxwell's equation. So, we have a free Dirac equation and a Maxwell's equation with the photon interacting with the electromagnetic field that term added. So, there is a free part for the psi there is a free part for A mu (Refer Time: 39:38) mu and there is an interaction term. So, these together will make sure that you have an equation of motion corresponding to the photon as well as the equation of motion corresponding to the charge the particle that you are considering through psi and these essentially is what is called the Quantum Electrodynamics QED.

And if you look at the Lagrangian it is clear the way we have been deriving the equation of motion from this that it will give you the correct equations of motion for the interacting ψ as well as the Maxwell's equation and then one thing we can do with this Lagrangian is to take consider the quantum field theory framework and then get the Feynman rules from this, that we had listed down that we had listed down earlier.

So, we have actually free part of this free propagator version of the ψ or the electrons or the Fermion particle that is represented by ψ that we can get from this and there is also an interaction term from which we can get the interaction vertices and these are the things that we need to discuss any interaction of ψ with electromagnetic field. Similarly we can also get the propagator for the photon from here and it; obviously, the interaction of the photon with the other one similar to these is exactly the same as the one which have we have just now set for the case of ψ .

(Refer Slide Time: 42:06)

We will look at other interactions so, there is electrodynamics that we talked about, but then there is a strong nuclear interaction and weak nuclear interaction can we describe these interactions also through the gauge symmetry, similar to what we discussed for the case of electrodynamics is one thing which we will see we will come to that in the next lecture.
