Lec 7: Schmidt Decomposition Method

Hello, welcome to lecture 5 of this course. This is lecture number 2 of module 2. In the last lecture, I have given you a brief technical introduction to quantum entanglement and I started discussing the so-called Schmidt decomposition method, which is a technique to characterize quantum entanglement, particularly in bipartite system. But to understand Schmidt decomposition method, we needed to learn singular value decomposition method, which we have done in the last lecture. In this lecture, I will first revise the singular value decomposition method by illustrating an example, and then we will begin discussing Schmidt decomposition method. So let us begin.

(Refer Slide Time: 02:34)

Find SVD of

$$A = \begin{pmatrix} 1 & 1 \\ 0 & 0 \\ i & i \end{pmatrix}; \quad (3 \times 2)$$

Solution

$$A^+A = \begin{pmatrix} 1 & 0 & -i \\ 1 & 0 & -i \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 0 \\ i & i \end{pmatrix} = \begin{pmatrix} 2 & 2 \\ 2 & 2 \end{pmatrix}$$

To find singular value decomposition of the matrix, A is equal to $1 \ 0 \ i \ 1 \ 0 \ i$. As you can see, this is a 3×2 matrix. That means 3 rows and 2 columns. So to find out the

SVD, singular value decomposition of this matrix. So first, let us calculate $A^T A$. Now, if A dagger, if you find, then you just have to take the transpose of the matrix A and then take the complex conjugate. So first row would become $1 \ 0$ minus I . Second row is also going to be $1 \ 0$ minus I . And the matrix A is $1 \ 0 \ 1 \ 0 \ 1$.

And if you do the multiplication, you will get $2 \ 2 \ 2 \ 2$. So as you can see, A dagger A is now a square matrix. You have started with a non-square matrix A and A dagger A is a square matrix of dimension 2 by 2 , 2 rows 2 columns.

(Refer Slide Time: 04:24)

Handwritten notes showing the calculation of eigenvalues and eigenvectors for $A^T A$:

Eigenvalues of $A^T A$:

$$\begin{cases} \lambda_1 = 4 \\ \lambda_2 = 0 \end{cases}$$

Characteristic equation:

$$\begin{vmatrix} 2-\lambda & 2 \\ 2 & 2-\lambda \end{vmatrix} = 0$$

$$\Rightarrow 2-\lambda = \pm 2$$

Eigenvector for $\lambda_1 = 4$:

$$v_1 = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 1 \end{pmatrix}$$

Eigenvector for $\lambda_2 = 0$:

$$v_2 = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ -1 \end{pmatrix}$$

Now, you can find out the eigenvalues of this matrix. Eigenvalues of A dagger A . If you set up the characteristic equation, you will find the eigenvalues as say λ_1 is equal to 4 . And λ_2 , you are going to the second eigenvalue, you will get it to be 0 . Okay, I just have solved this equation. 2 minus λ $2 \ 2$ 2 minus λ is equal to 0 .

And from this, the characteristic equation you can set up, you will get 2 minus λ is equal to plus minus 2 . So this is going to give you the eigenvalues as 4 and 0 . Now let us find out the eigenvectors corresponding to these two eigenvalues. So eigenvectors, eigenvectors vector for say λ_1 is equal to 4 . I think all of you know it. If you do the calculation, you will find the eigenvector for λ_1 is equal to v as 1 by root $2 \ 1 \ 1$.

And similarly, you can show that the eigenvector, eigenvector for λ_2 is equal to 0 .

This is for lambda 1. For lambda 2 is equal to 0, v2, the eigenvector would become 1 by root 2 1 minus 1.

(Refer Slide Time: 05:31)

Handwritten notes showing the calculation of eigenvectors and the sigma matrix. The text reads: "Eigenvector for $\lambda_2 = 0$ ". Below this, the eigenvector v_2 is given as $\frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ -1 \end{pmatrix}$. The matrix V is then shown as $\frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$. Finally, the sigma matrix Σ is calculated as $\begin{pmatrix} \sqrt{\lambda_1} & 0 \\ 0 & \sqrt{\lambda_2} \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} 2 & 0 \\ 0 & 0 \\ 0 & 0 \end{pmatrix}$.

So this can immediately give you the v matrix that we discussed. The capital V matrix would become, you can construct it from these eigenvectors. So first you write v1, v1 is 1 by root 2 1 1 and v2 is 1 by root 2 1 minus 1. So this is going to be your v matrix.

And the sigma matrix is easy to get because already we have got the eigenvalues. So this is going to be a 3 by 2 matrix. It has the same dimension as that of the original matrix A. And it would be square root of lambda 1 0 0 square root of lambda 2 0 0. So therefore, the sigma matrix would become lambda 1 is equal to 4. So square root of lambda 1 is 2 0 0 0 0. This is the sigma matrix.

(Refer Slide Time: 07:32)

Handwritten notes showing the calculation of eigenvalues and an eigenvector for the matrix AA^T . The text reads: "Eigenvalues of AA^T :". The matrix AA^T is given as $\begin{pmatrix} 2 & 0 & -2i \\ 0 & 0 & 0 \\ 2i & 0 & 2 \end{pmatrix}$. The eigenvalues are listed as $\lambda_1 = 4, \lambda_2 = 0, \lambda_3 = 0$. For $\lambda_1 = 4$, the corresponding eigenvector u_1 is given as $\frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 0 \\ i \end{pmatrix}$.

Now, what about the capital U matrix? What about this capital U matrix? So to do that, you have to find out $A A^\dagger$ and if you do the mathematics, you can show calculation. If you do, you will find that the $A A^\dagger$ would become $\begin{pmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 2 \end{pmatrix}$.

And again, you have to find out the corresponding eigenvectors. Again, here the eigenvalues of $A A^\dagger$ is going to be the same eigenvectors. Sorry, eigenvalues, I should first find out the eigenvalues. Eigenvalues are going to be the same as that of $A A^\dagger$. Only thing is that you can have an extra eigenvalue here. So what you are going to get is eigenvalues of $A A^\dagger$. Again, you can get it by setting up the characteristic equation. You are going to get the eigenvalues as λ_1 is equal to 4, λ_2 is equal to 0. You will get three eigenvalues because it's a three by three matrix and λ_3 is going to be equal to 0.

And corresponding eigenvectors you can find it out. For λ_1 is equal to say 0. Ok, so first let me do it for λ_1 is equal to 4, right? So λ_1 is equal to 4. You will get eigenvectors as u_1 is equal to $\frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 1 \\ 0 \end{pmatrix}$.

(Refer Slide Time: 07:59)

The slide shows the following handwritten equations:

$$\lambda_2 = 0, \quad u_2 = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}$$

$$\lambda_3 = 0, \quad u_3 = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 0 \\ -i \end{pmatrix}$$

And for λ_2 is equal to 0, you can get, you can show that the eigenvector is $\begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}$. And for λ_3 is equal to 0, these eigenvectors are, is going to be u_3 is equal to $\frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 0 \\ -i \end{pmatrix}$.

(Refer Slide Time: 09:01)

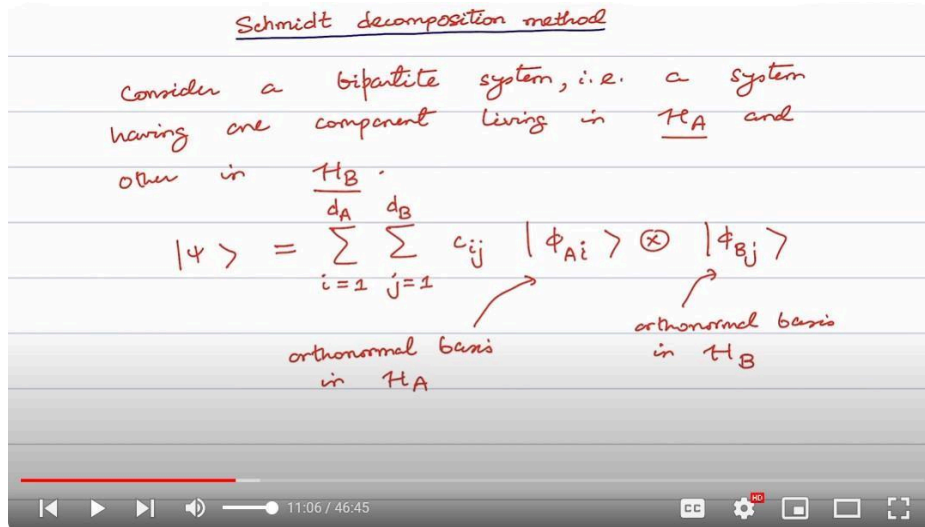

$$\lambda_3 = 0, \quad u_3 = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 0 \\ -i \end{pmatrix}$$
$$U = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 0 & 1 \\ 0 & \sqrt{2} & 0 \\ i & 0 & -i \end{pmatrix}$$
$$A = U \Sigma V^\dagger$$

So therefore this capital U matrix, you will get it as $\frac{1}{\sqrt{2}}$. It is going to be constructed from these three eigenvectors u_1 , u_2 and u_3 . So just let me write it column wise. It will be $\frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 0 & 1 \\ 0 & \sqrt{2} & 0 \\ i & 0 & -i \end{pmatrix}$. Ok, so this is your capital U.

So this way you will be able, you are then able to get the singular value decomposition of the matrix A. And that would be capital U sigma v dagger. You have found out this matrix V, V matrix you have found out. So you just have to take the Hermitian conjugate of that. And you can actually verify it taking the matrix products of these three matrices. Then if you work out, you will be able to get the original matrix A.

Now having learned the required mathematical tools, we are ready to discuss the Schmidt decomposition method.

(Refer Slide Time: 11:06)

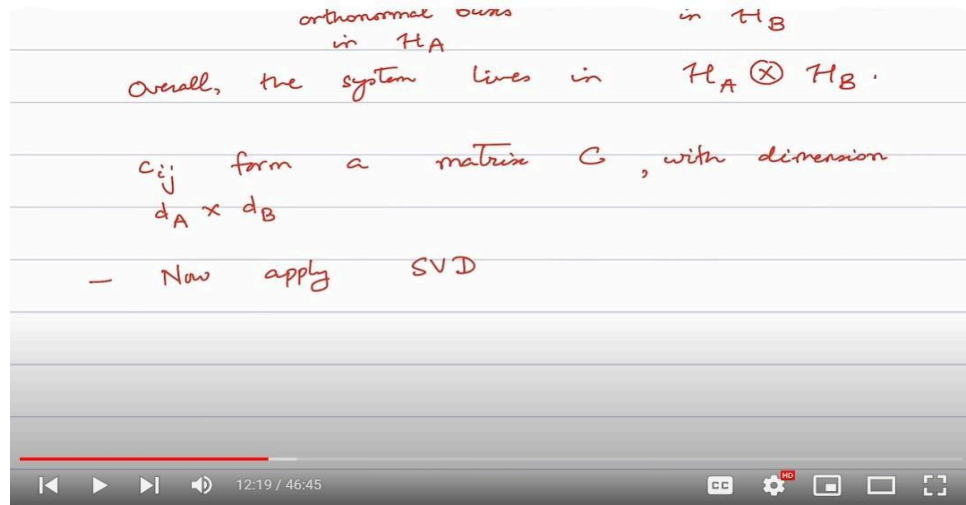

Let us consider a bipartite system and a bipartite system as you know has two components. That is a system having two components. Out of these two components having one component living in, living in the Hilbert space \mathcal{H}_A . And other living in the Hilbert space \mathcal{H}_B . So it is a system consisting of two subsystems A and B.

And any arbitrary state ket ψ of the system can be expressed as it is a pure state. So I can express it as a direct product state. I am going to explain all the terms one by one. Summation is going from i is equal to one to d_A . Where d_A is the dimension of the Hilbert space \mathcal{H}_A .

And this other summation go from j is equal to one to d_B . d_B is the dimension of the Hilbert space \mathcal{H}_B . And these coefficients are C_{ij} . And I have this basis ket ϕ_{Ai} direct product with ϕ_{Bj} . Where ϕ_{Ai} are the orthonormal basis.

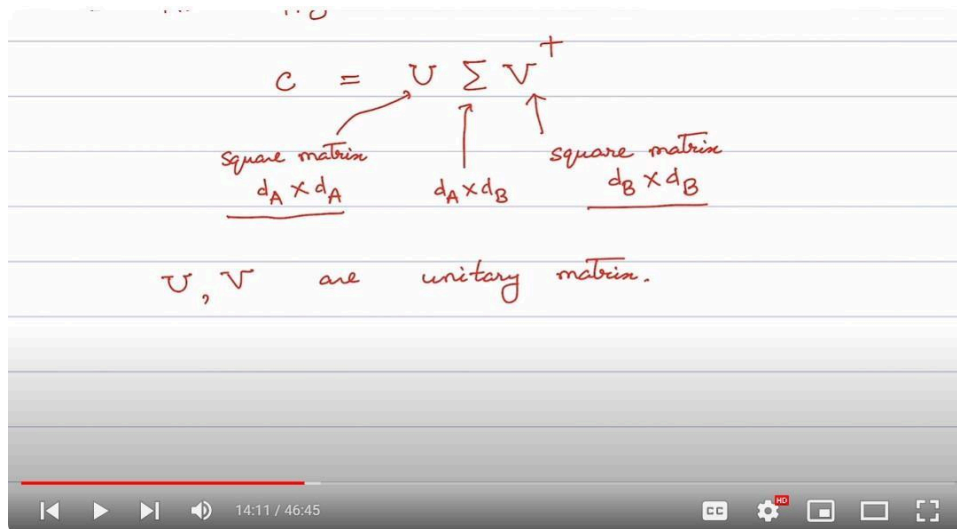

These are the orthonormal basis in the Hilbert space \mathcal{H}_A . On the other hand ϕ_{Bj} are the orthonormal basis in the Hilbert space \mathcal{H}_B . Okay? And overall the system lives in the Hilbert space. Overall the system lives in the Hilbert space \mathcal{H}_A tensor product \mathcal{H}_B .

(Refer Slide Time: 12:19)

Alright. Now you see these coefficients C_{ij} they form a matrix C with the dimension. Let me write here C_{ij} this coefficient form a matrix say capital C with dimension. That means the size of the matrix is d_A cross d_B . That means it has d_A number of rows and d_B number of columns. That's the size of the matrix. As you can see this may be a non-square matrix. And in that case from singular value decomposition one can apply.

(Refer Slide Time: 14:11)

Now apply the singular value decomposition to express this matrix C in the form capital U , capital Σ and. Now here this capital U is a square matrix as you know from SVD

method already you have learned. It's a square matrix with size d_A cross d_A . As you have seen that this capital C is a matrix with size d_A cross d_B . So capital U is a matrix with size d_A cross d_B . While V is a square matrix again even its hermitian conjugate is also a square matrix. It's a square matrix with size or dimension d_B cross d_B .

On the other hand this capital sigma it is a non-square matrix. It may be a non-square matrix because not necessarily that you know A is not equal to B . This SVD method can be applied even to a square matrix as well. But in general this sigma matrix has a size d_A cross d_B . It's a non-square matrix which has non-zero elements along the main diagonal. And both this capital U , both this capital U and capital V are unitary matrix. And it's very important to remember this U and V are unitary matrix.

(Refer Slide Time: 15:44)

U, V are unitary matrix.

$$|\psi\rangle = \sum_{i=1}^{d_A} \sum_{j=1}^{d_B} c_{ij} |\phi_{A_i}\rangle \otimes |\phi_{B_j}\rangle$$

\downarrow

$$C = U \Sigma V^\dagger$$

$$|\psi\rangle = \sum_{i=1}^{d_A} \sum_{j=1}^{d_B} \sum_{k=1}^{\min(d_A, d_B)}$$

So we can therefore express, let me write this once again. Therefore we can express this ket psi state which we have written as say I goes from 1 to d_A , J is equal to 1 to d_B . I

have C_{ij} ϕ_{Ai} cross that's a transfer product with ϕ_{Bj} . Here C_{ij} is a matrix C is I can express it using the SVD method as $U \Sigma V^\dagger$.

(Refer Slide Time: 17:05)

The slide shows the following handwritten equations:

$$C = U \Sigma V^\dagger$$

$$|\psi\rangle = \sum_{i=1}^{d_A} \sum_{j=1}^{d_B} \sum_{k=1}^{\min(d_A, d_B)} u_{ik} d_{kk} v_{jk}^* |\phi_{Ai}\rangle \otimes |\phi_{Bj}\rangle$$

Define:

$$|u_{A,k}\rangle = \sum_{i=1}^{d_A} u_{ik} |\phi_{Ai}\rangle$$

$$|v_{B,l}\rangle$$

The slide also includes a video player interface at the bottom with a progress bar at 17:05 / 46:45 and various control icons.

So this ket ψ can be expressed as ket ψ is equal to summation i is equal to 1 to d_A , summation j is equal to 1 to d_B and I will now express this matrix capital C in terms of components C_{ij} I am just expressing in terms of matrix. So this can also I express in this form. I am going to write another sum going from say k is equal to 1 to the dimension would be such that it will go from the minimum of d_A and d_B . All these things will be clear to you once I discuss some example later on. And this coefficient C_{ij} in terms of this matrix C , I can express in terms of capital U , capital Σ and V as follows.

I will write the sum as this $U_{ik} d_{kk}$ because Σ is a diagonal matrix. Its main diagonal only I am going to consider and then I have V_{jk}^* it's a hermitian conjugate and we are having the other parts as ϕ_{Ai} cross ϕ_{Bj} . Okay. Now let me define to simplify this big expression I can define let me define quantities. Say ket $u_{A,k}$, small $u_{A,k}$ is equal to summation i is equal to 1 to d_A $U_{ik} \phi_{Ai}$ and $V_{B,k}$ $V_{B,k}$.

(Refer Slide Time: 18:38)

$$\begin{aligned}
 & \bullet \quad |u_{A,k}\rangle = \sum_{i=1}^{d_A} u_{ik} |\phi_{Ai}\rangle \quad \text{form orthonormal basis of } \mathcal{H}_A \\
 & \bullet \quad |v_{B,k}\rangle = \sum_{j=1}^{d_B} v_{jk} |\phi_{Bj}\rangle \quad \text{form orthonormal basis of } \mathcal{H}_B \\
 & |\psi\rangle = \sum_{k=1}^{\min(d_A, d_B)} d_{kk} |u_{Ak}\rangle \otimes |v_{Bk}\rangle
 \end{aligned}$$

Let me write another ket phi VBk is equal to j is equal to 1 to dB Vjk star phi Bj. Okay. Now due to unitarity of capital U and capital V this ket uak and ubk they form orthonormal basis. Let me write here form orthonormal basis of the Hilbert space HA. And similarly VBk form orthonormal basis of HB. Okay. So using this definition we can obtain this ket psi in this form is going from k is equal to 1 to minimum of dA and dB. Whatever is minimum out of dA and dB then you have this dkk uak tensor product with VBk. Okay.

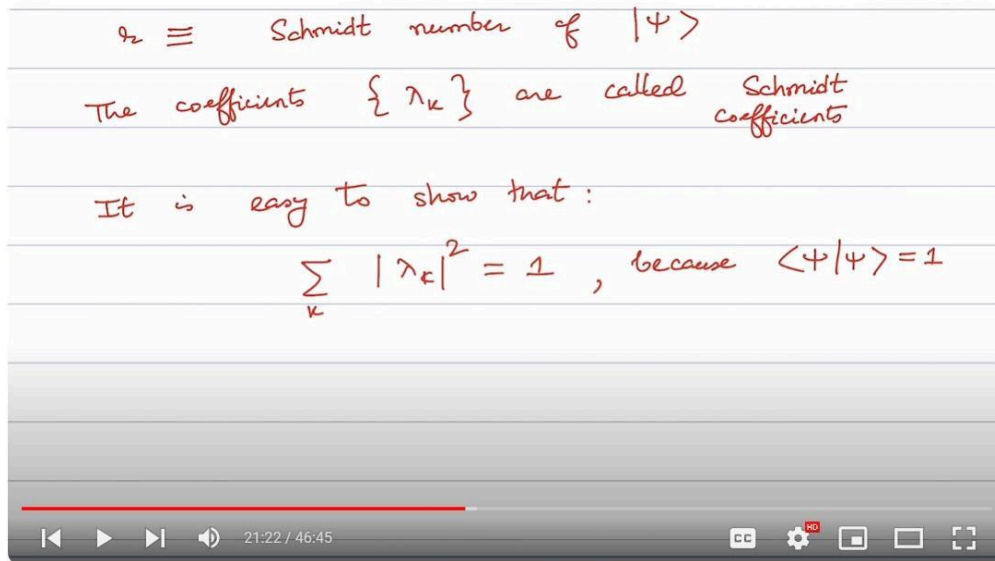

(Refer Slide Time: 20:16)

$$\begin{aligned}
 |\psi\rangle &= \sum_{k=1}^{r_2} \lambda_k |u_{Ak}\rangle \otimes |v_{Bk}\rangle \\
 \text{where } \lambda_k &= d_{kk} \text{ and } r_2 = \min(d_A, d_B) \\
 r_2 &: \text{ refers to the number of non-zero diagonal elements in } \Sigma \\
 r_2 &\equiv \text{ Schmidt number of } |\psi\rangle
 \end{aligned}$$

So to write it in a more convenient form I can write this in a more convenient form. Let me write psi is equal to k is equal to 1 to R lambda k uak direct product or tensor product

with λ_k . Where λ_k as you can see is equal to d_{kk} and R is equal to minimum of d_A d_B . Actually let me explain this quantity R a little bit. This refer to R refers to the number it refers to the number of non-zero diagonal elements. Non-zero diagonal elements of the or in the capital sigma matrix. And this has a name and this quantity is called R is named as the Schmidt number. It's called it's an important quantity. This is called Schmidt number of the state ket psi.

(Refer Slide Time: 21:22)

And the coefficients, the coefficients lambdas, the coefficients lambda k has also a name. R called Schmidt coefficients. It is easy to show, easy to show that I encourage you to do it yourself. It's very trivial that summation over k mod lambda k square is equal to 1. And you can show it because of the fact that this state psi ket psi is normalized. So using this fact you can easily show that summation over lambda k square mod lambda k square is equal to 1. Now before I go further just quickly let me also write down the density operator for the bipartite system.

Using this new form where we have written the ket psi in this particular form and this form is known as the Schmidt form. This is what is basically Schmidt decomposition. It may be useful to write the density operator for the bipartite system using this Schmidt decomposition form.

(Refer Slide Time: 22:52)

$$|\psi\rangle = \sum_{k=1}^R \lambda_k |u_{Ak}\rangle \otimes |v_{Bk}\rangle$$

$$\hat{\rho} = \sum_k \sum_L \lambda_k \lambda_L^* |u_{Ak}\rangle \langle u_{AL}| \otimes |v_{Bk}\rangle \langle v_{BL}|$$

The Schmidt decomposition form that we have is this ket psi is equal to k is equal to 1 to R lambda k U a k tensor product with V b k. This is the so called Schmidt decomposition form. And the corresponding density operator you can easily work out yourself and you can see that it would be summation over k and summation over L lambda k lambda L star U a k the bra U a L direct product with ket V k and bra V b L. I think you can easily follow it. It's easy to follow from the form that I have written from here. Using this you can easily get it.

So we have seen that every bipartite system in a pure state can be rewritten in terms of Schmidt decomposition. Let us now illustrate this method using a quick example.

(Refer Slide Time: 25:03)

Example @ Schmidt decomposition

$$|\psi\rangle = \frac{1}{2} \left[|\phi_{A2}\rangle |\phi_{B1}\rangle + |\phi_{A1}\rangle |\phi_{B2}\rangle + i |\phi_{A3}\rangle |\phi_{B1}\rangle + i |\phi_{A3}\rangle |\phi_{B2}\rangle \right]$$
 This can be rewritten as:

$$|\psi\rangle = \sum_{i=1}^3 \sum_{j=1}^2 c_{ij} |\phi_{Ai}\rangle \otimes |\phi_{Bj}\rangle$$

Consider a bipartite state given by this ket. ket psi is equal to half phi a 1 phi b 1 plus phi a 1 phi b 2. All these phi's are orthonormal states phi b 2 plus i phi a 3 phi b 1 plus i phi a 3 phi b 2. Okay this is the ket state given to you. Now this can be rewritten. This particular given state can be rewritten as follows. It can be rewritten as ket psi is equal to

summation i is equal to 1 to 3 and summation j is equal to 1 to 2 $c_{ij} \phi_i$. As you can see ϕ_i here i goes from 1 to 3 right as you can see and, in the process, as you can see ϕ_2 is equal to 0. But anyhow the suffix i goes from 1 to 3 it would be direct product with ϕ_j and j goes from 1 to 2 as you can see here in this expression. We have ϕ_1 and ϕ_2 is there so it goes j goes from that's why from 1 to 2.

(Refer Slide Time: 26:51)

$$C = \frac{1}{2} \begin{pmatrix} 1 & 1 \\ 0 & 0 \\ i & i \end{pmatrix} ; \text{ 3x2 matrix}$$

$$C = U \Sigma V^T$$

$$U = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 0 & 1 \\ 0 & \sqrt{2} & 0 \\ i & 0 & -i \end{pmatrix}$$

So obviously this is a pure state and this coefficients c_{ij} form a matrix. This coefficients c_{ij} would be 1 1 0 0 i i . So this is a non-square matrix. This is a 3 by 2 matrix 3 rows it's a 3 by 2 matrix 3 rows and 2 columns.

Okay. And this matrix we can express in the form of SVD. In fact we have actually already worked out the singular value decomposition of this matrix a few minutes back. And we can use those results now from the example that we have done in the context of singular value decomposition. We have exactly used this particular matrix C . Let me write here instead of c_{ij} let me write capital C that's the matrix I have formed from this coefficients c_{ij} . And now this matrix can be written in the singular value decomposition form where we already worked out.

It would be U capital sigma V Hermitian conjugate of the V matrix. We have already worked out this capital U matrix in the example that we have done a little while back. It is $1/\sqrt{2}$ 1 0 1 0 $\sqrt{2}$ 0 i 0 minus i .

(Refer Slide Time: 27:56)

$$\Sigma = \begin{pmatrix} 2 & 0 \\ 0 & 0 \\ 0 & 0 \end{pmatrix} = 2 \begin{pmatrix} 1 & 0 \\ 0 & 0 \\ 0 & 0 \end{pmatrix}$$

$$V = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$$

$$|\psi\rangle = \sum_{k=1}^r \lambda_k |u_{Ak}\rangle \otimes |v_{Bk}\rangle$$

And capital sigma is 2 0 0 0 0 0. So this capital sigma matrix has only one non-zero diagonal element. So or we can write it as 1 0 0 0 0 0. And this matrix V capital V matrix we worked out as 1 by root 2 1 1 1 minus 1. We want to write ket psi in the Schmidt decomposition form as follows. ket psi is equal to summation k is equal to 1 to r lambda k U ak tensor product with V bk small v bk.

(Refer Slide Time: 29:55)

Now, $r = 1$, as the number of non-zero elements in $\Sigma = 1$

$$|\psi\rangle = \sum_{k=1}^1 \lambda_k |u_{Ak}\rangle \otimes |v_{Bk}\rangle$$

$$\Sigma = \begin{pmatrix} 2 & 0 \\ 0 & 0 \\ 0 & 0 \end{pmatrix}, \quad \begin{matrix} \lambda_k = d_{kk} \\ \lambda_k = 2 \end{matrix}$$

$$\lambda_1 = 2, \quad \sum_k \lambda_k^2 = 1$$

$$\Rightarrow \lambda_1 = 1$$

Now r is equal to 1 here. Now r is equal to 1 why because the number of non-zero elements in the sigma matrix is 1. That's why r is equal to 1 as per our definition of r that's called the Schmidt number. r is equal to 1 as the number of non-zero elements in sigma matrix is equal to 1. So ket ψ is equal to in the Schmidt decomposition form summation k is equal to 1 to 1 $\lambda_k U_k$ tensor product with V_k .

Now what about λ_k ? What is this? Now from the sigma matrix let me write the sigma matrix we obtain as $\begin{pmatrix} 2 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}$. And because λ_k is equal to d_{kk} it may occur to that you should take λ_k is equal to 2. But because k runs from 1 to 1 that means we have only one lambda that is λ_1 . So you may write λ_1 is equal to 2 but you have to be careful here because lambda has to satisfy this equation λ^2 is equal to 1. Right and this means that we have to take the normalized form of lambda and λ_1 you better take it as 1.

(Refer Slide Time: 31:20)

$$\Rightarrow \lambda_1 = 1$$

$$|\psi\rangle = \lambda_1 |u_{A1}\rangle \otimes |v_{B1}\rangle$$

$$|u_{Ak}\rangle = \sum_{i=1}^3 u_{ik} |\phi_{Ai}\rangle$$

$$\Rightarrow |u_{A1}\rangle = u_{11} |\phi_{A1}\rangle + u_{21} |\phi_{A2}\rangle + u_{31} |\phi_{A3}\rangle$$

So therefore ket ψ we should write as the summation is has no meaning now only we have only one term that is λ_1 only one coefficient λ_1 . And other terms are U

a1 direct product with V b1. So this is the Schmidt decomposition form of the example that we have considered but now let us find out what is U a1 and what is ket V b1.

Now as per the definition of ket U a1 k we had summation i is equal to 1 to 3 small u i k phi a i. And this we can now because k is equal to 1 therefore we can now write U a1 is equal to if I open it up I will have U11 phi a1 plus U21 phi a2 plus U31 phi a3. Right now the fact is that U a2 phi a2 ket phi a2 is equal to 0.

(Refer Slide Time: 32:33)

$$\begin{aligned}
 \Rightarrow |u_{A1}\rangle &= u_{11} |\phi_{A1}\rangle + u_{21} \underbrace{|\phi_{A2}\rangle}_{=0} + u_{31} |\phi_{A3}\rangle \\
 &= u_{11} |\phi_{A1}\rangle + u_{31} |\phi_{A3}\rangle \\
 U &= \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 0 & 1 \\ 0 & \sqrt{2} & 0 \\ i & 0 & -i \end{pmatrix} \Rightarrow u_{11} = \frac{1}{\sqrt{2}}, \quad u_{31} = \frac{i}{\sqrt{2}} \\
 |u_{A1}\rangle &= \frac{1}{\sqrt{2}} \left(|\phi_{A1}\rangle + i |\phi_{A3}\rangle \right)
 \end{aligned}$$

So I will have U11 phi a1 plus U31 phi a3. Now look at the matrix elements of capital U. Capital U matrix if you recall this was 1 by root 2 1 0 1 0 root 2 0 i 0 minus i. So from here you can easily see that U11 is equal to 1 by root 2 and U31 is equal to i by root 2. So therefore you have the ket U a1 is equal to 1 by root 2 phi a1 plus i phi a3.

(Refer Slide Time: 34:15)

$$|u_{A1}\rangle = \frac{1}{\sqrt{2}} (|\phi_{A1}\rangle + i|\phi_{A3}\rangle)$$

Similarly,

$$|v_{B1}\rangle = \frac{1}{\sqrt{2}} (|\phi_{B1}\rangle + |\phi_{B2}\rangle)$$

$$|\psi\rangle = |u_{A1}\rangle |v_{B1}\rangle$$

$$= \frac{1}{\sqrt{2}} (|\phi_{A1}\rangle + i|\phi_{A3}\rangle) \otimes \frac{1}{\sqrt{2}} (|\phi_{B1}\rangle + |\phi_{B2}\rangle)$$

$$= \frac{1}{2} (|\phi_{A1}\rangle + i|\phi_{A3}\rangle) \otimes (|\phi_{B1}\rangle + |\phi_{B2}\rangle)$$

Okay what about V_{B1} ? Similarly you can work it out I leave it to you. Similarly you can show that ket V_{B1} is equal to $\frac{1}{\sqrt{2}} (|\phi_{B1}\rangle + |\phi_{B2}\rangle)$. So we can write the given ket ψ in the Schmidt form as follows. ket ψ is equal to $U_{A1} V_{B1}$ and if I write U_{A1} ket U_{A1} is $\frac{1}{\sqrt{2}} (|\phi_{A1}\rangle + i|\phi_{A3}\rangle)$ tensor product. $\frac{1}{\sqrt{2}} (|\phi_{B1}\rangle + |\phi_{B2}\rangle)$ or half ket ϕ_{A1} plus i ket ϕ_{A3} tensor product with ϕ_{B1} ket ϕ_{B1} plus ket ϕ_{B2} .

(Refer Slide Time: 35:48)

$$= \frac{1}{\sqrt{2}} (|\phi_{A1}\rangle + i|\phi_{A3}\rangle) \otimes \frac{1}{\sqrt{2}} (|\phi_{B1}\rangle + |\phi_{B2}\rangle)$$

$$= \frac{1}{2} \underbrace{(|\phi_{A1}\rangle + i|\phi_{A3}\rangle)}_{\text{sub-system A}} \otimes \underbrace{(|\phi_{B1}\rangle + |\phi_{B2}\rangle)}_{\text{sub-system B}}$$

Here, $r_2 = 1 \Rightarrow$ it is NOT an entangled state

$r_2 > 1 \Rightarrow$ the bipartite state is NOT separable, it is entangled.

Now you please see that I am able to write the Schmidt form here in such a way that this part refers to the subsystem or one component called A component A or subsystem A on the other hand this one I write for subsystem B. So these states are separable here and in this example here the so called Schmidt number R is equal to 1 and the state is separable so it implies so I can conclude that if R is equal to 1 it is not an entangled state it's a

separable state. It's not an entangled state. On the other hand if you find that for a given bipartite state R is greater than 1 that may imply that the bipartite state is not separable. In other words it is entangled.

Ok now some final words on Schmidt decomposition there are various forms of Schmidt decomposition in the literature.

(Refer Slide Time: 37:53)

The image shows a video player with handwritten mathematical notes in red ink. The notes are as follows:

$$|\psi\rangle = \sum_{i=1}^R \sqrt{s_i} |u_{Ai}\rangle \otimes |v_{Bi}\rangle$$

with $\sum_i s_i = 1, s_i > 0$

$R \in \mathbb{N}$, is the Schmidt number of $|\psi\rangle$

$$|\psi\rangle = \sum_{k=1}^R \lambda_k |u_{Ak}\rangle \otimes |v_{Bk}\rangle$$

$\lambda_k \rightarrow \sqrt{s_k}$

At the bottom of the video player, there is a progress bar and controls. The time displayed is 37:53 / 46:45.

For example sometime you may see this particular form say ket psi is equal to summation i is equal to 1 to R square root of S_i u_{Ai} tensor product with v_{Bi} this is for a bipartite system with the condition that with summation sum over S_i is equal to 1 where S_i is greater than 0 these are called Schmidt coefficient just like the number lambda i's and R is basically a natural number it's a number and it is called R is the Schmidt number of the state ket psi.

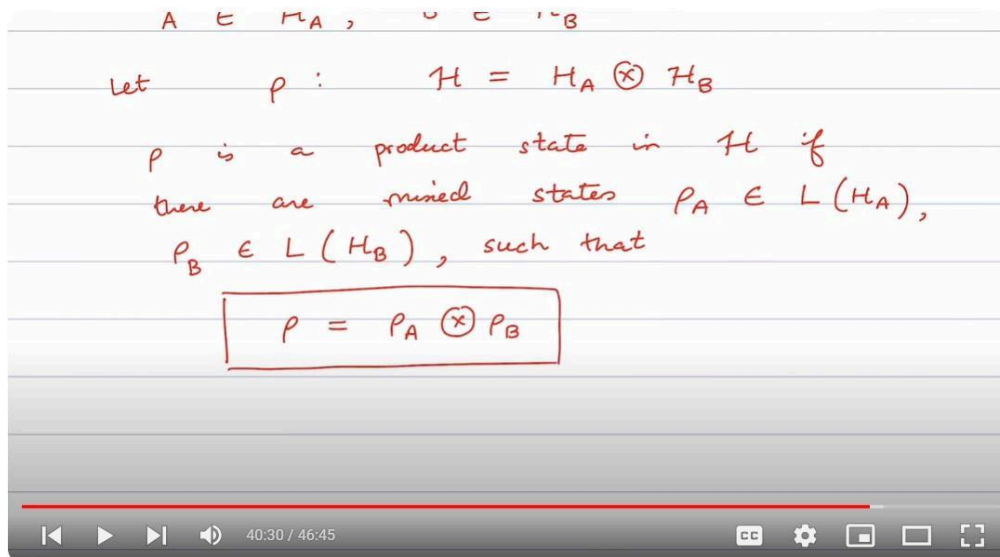

In fact it is basically the same thing we wrote for Schmidt decomposition of ket psi just to remind once again as a final comment we have written and we are going to take this particular form in this course of Schmidt decomposition where k goes from 1 to R lambda k u_{Ak} direct product or tensor product with v_{Bk} ok so this is the form we are going to use in this course and if you look at the correspondence here lambda k refers to square root of S_k in the previous expression and lambda k is termed as Schmidt coefficient.

(Refer Slide Time: 38:56)

The image shows a video player interface with handwritten notes in red ink. The title is "Entanglement of mixed states". The main equation is $\hat{\rho} = \sum_j p_j |\phi_j\rangle \langle \phi_j|$. Below it, it says $A \in \mathcal{H}_A, B \in \mathcal{H}_B$. The final line says "Let $\rho : \mathcal{H} = \mathcal{H}_A \otimes \mathcal{H}_B$ ". The video player controls at the bottom show a progress bar at 38:56 / 46:45.

Now before I end this lecture let me now briefly talk about entanglement of mixed states we already know that the mixed state can be represented by a density operator say rho is equal to sum over j Pj ket phi j bra phi j now consider a composite system where it has consisting of say subsystem A and B subsystem A belongs to the Hilbert space HA and the system B belongs to the Hilbert space subsystem B belongs to the Hilbert space HB now let rho be a mixed state over the Hilbert space H is equal to HA tensor product with HB.

(Refer Slide Time: 40:30)

A state ρ is a product state in H in the Hilbert space H if there are mixed states ρ_A and ρ_B such that $\rho = \rho_A \otimes \rho_B$. Here, ρ_A is a density operator on a Hilbert space H_A , and ρ_B is a density operator on a Hilbert space H_B . Both ρ_A and ρ_B belong to the set of linear operators on their respective Hilbert spaces.

What about the case where we have a number of such product states forming a mixed state? How can we characterize if they are separable or not? There is a concept called convexity which may be useful in this context. Let us discuss it.

(Refer Slide Time: 42:13)

Convexity

$\rho_1, \rho_2, \dots, \rho_n \in L(H)$, then the mixed state $\rho \in L(H)$ is separable if there are convex weights $w_i > 0$ such that $\sum w_i = 1$ such that

$$\rho = \sum_{i=1}^n w_i \rho_i$$

Say we have $\rho_1, \rho_2, \dots, \rho_n$ number of product states are there that belong to the set of product of linear operator in the Hilbert space H and in that case then the mixed state which is formed out of this all this product states belonging to the linear operator in the Hilbert space H is separable if there are convex weights. I will explain what it is there are convex weights denoted by say w_i which is greater than zero and also sum of all w_i 's is equal to one such that ρ is equal to summation i to n , $w_i \rho_i$.

(Refer Slide Time: 43:47)

$$\rho = \sum_{i=1}^n w_i \rho_i$$

By convexity:

For every pair $\hat{\rho}_1, \hat{\rho}_2 \in \{\hat{\rho}_i\}$ the set of operators $\{\hat{\rho}_i\}$ form a convex set if

$\rho = w_1 \rho_1 + w_2 \rho_2$

 $, w_1 + w_2 = 1$

Now what I mean by convexity is the following by convexity I mean the following I mean that for every pair for every pair ρ_1, ρ_2 which belongs to one of the ρ_i 's the set of operators the set of operators $\rho_1, \rho_2, \dots, \rho_i$ so they form a for every pair ρ_1, ρ_2 the set of operators ρ_i form a convex set if ρ you can write as $w_1 \rho_1 + w_2 \rho_2$ so this is valid for every component

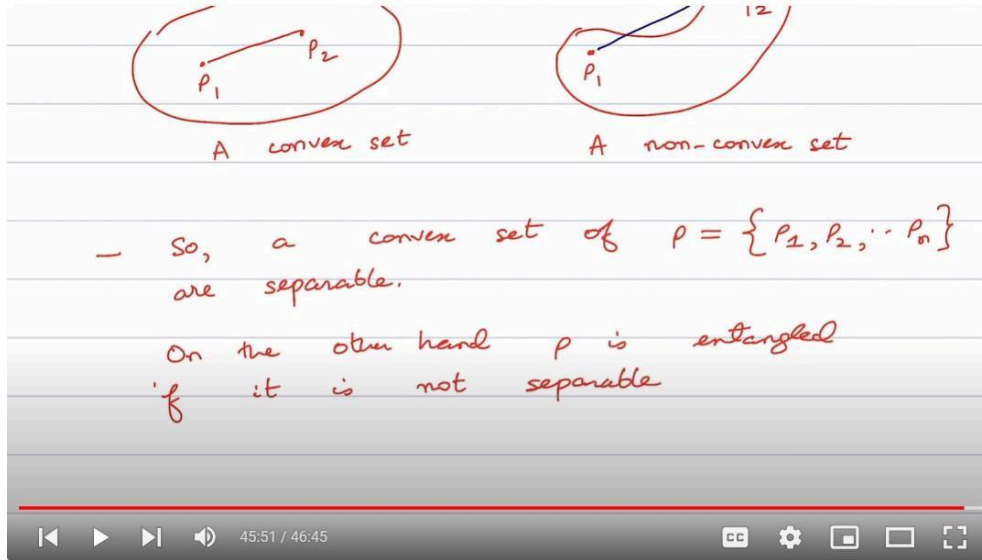

that is belonging to the set of operators ρ_1, ρ_2 up to ρ_n you can write such relations of this type if you can do that with the condition $w_1 + w_2 = 1$ so this is what we mean by convexity and this is a very simple meaning

(Refer Slide Time: 45:20)

it means that for any two members form a convex set say ρ_1, ρ_2 they form a convex set if they can be connected by a straight line without leaving the set so this is what I mean by a convex set so as you can see in this convex set ρ_1 and ρ_2 can be connected to each other without leaving the set on the other hand by a non-convex set I mean the following say I have this member here ρ_1 and this is ρ_2 and if I want to connect ρ_1 and ρ_2 by a straight line so as you can see I have to leave the set right as you can see I have to leave the set so it's an example of a non-convex set so a convex set of ρ is equal to ρ_1, ρ_2 up to ρ_n are separable that means in simple words if the product states ρ_1, ρ_2 up to ρ_n form a convex set then they are separable.

(Refer Slide Time: 45:51)

On the other hand ρ is entangled if it is not separable. Let me stop now in this lecture we have learnt an important characterizing method of quantum entanglement in terms of the so called Schmidt decomposition method in the next lecture I am going to discuss the EPR paradox and Bayles inequalities and so on this may help you to get an intuitive understanding of quantum entanglement so see you in the next lecture thank you so much you.
