**Lecture - 12**  
**Line surface area and volume elements**  
**in Spherical Polar Coordinates**

In the previous lecture, we looked at the Line surface area and volume element in Cartesian and cylindrical coordinates. In this lecture, we will focus on a spherical coordinate system.

(Refer Slide Time: 00:27)

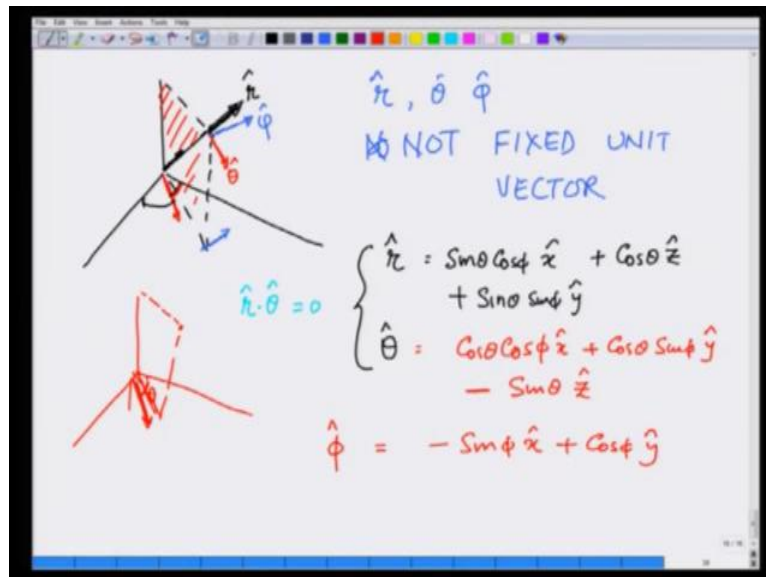

In a spherical coordinate system, a point is specified by its distance from the origin, which I will call  $r$  and if I make the plane containing this point and the  $z$  axis. So, this is  $r$ , the distance from the origin to the point. In this plane, if I measure the angle from the  $z$  axis to this line joining origin and the point, this angle is given as  $\theta$  and the angle in this plane, this entire plane, this entire plane makes from the  $x$  axis is known as  $\phi$ .

So, this point is specified by  $r$ ,  $\theta$ , and  $\phi$ , to cover the entire range or entire space, we let  $r$  go from 0 to infinity,  $\theta$  varies from 0 to  $\pi$ . That means, it varies from plus  $z$  to minus  $z$  axis and then let  $\phi$  vary from 0 to  $2\pi$  and that covers the entire space. So, these are going to be the ranges of the variables. Relationship between  $r$ ,  $\theta$ , and  $\phi$

with Cartesian coordinates is going to be  $r$ , you can see immediately is nothing but  $x^2 + y^2 + z^2$ .

Theta is the angle between the  $z$  axis and  $r$ , and therefore you can immediately see that cosine of theta is going to be given by  $z/r$  or  $z/\sqrt{x^2 + y^2 + z^2}$ . Third, this  $r$  has a projection in the  $x-y$  plane, which is this red thick line, which is nothing but  $r \sin \theta$ . And if you have studied the previous lecture well, this  $r \sin \theta$  is nothing but equivalent to cylindrical coordinate  $S$ . And therefore,  $x$  coordinate is nothing but  $r \sin \theta \cos \phi$ ,  $y$  coordinate is nothing but  $r \sin \theta \sin \phi$  and this immediately tells you tangent of  $\phi$  is exactly like the cylindrical coordinates  $y/x$ .

(Refer Slide Time: 03:44)

How about the unit vectors? So, I am going to have unit vectors in direction  $r$  like this. In direction  $\theta$ , which is going to be in this plane containing the point on the  $z$  axis, it is going to be perpendicular to the  $r$  and like this. If I transport it parallel to itself, it is going to be pointing down like this and  $\phi$  vector is going to be like the cylindrical coordinate  $\phi$  vector like this, which is perpendicular to  $r$   $\theta$  and  $\phi$ .

So, let us write this  $r$  unit vector,  $\theta$  unit vector and  $\phi$  unit vector and this forms a coordinate system, which is three unit vectors are perpendicular to each other, but none of these vectors  $r$  or  $\theta$  or  $\phi$  are fix in space. So, they are not fix unit vectors. So, as you change the position, they also change. Let us write them in terms of  $x$   $y$  in  $z$  unit

vectors,  $\vec{r}$  is pointing this way and we have already seen that, if I take the unit vector, its distance is 1, the z component is nothing but cosine of theta.

So, cosine of theta z plus projection in the x y plane is sine theta, hence its x component is going to be sine theta cosine phi as we saw in the previous slide. So, x component is sine theta, cosine of phi in the x direction plus y component is going to be sine theta, sine of phi in the y direction, this is  $\hat{r}$  unit vector. How about theta unit vector? Theta unit vector is perpendicular to  $\vec{r}$ , so therefore, it makes an angle and let me make it, show it by red out here or make it separately.

This is my point, theta is pointing down making an angle theta from the x y plane and therefore, in the x y plane, its component is cosine theta. So, it is going to be cosine of theta and then again that has a component cosine phi in the x direction plus cosine of theta, sine of phi in the y direction. In the z direction, it has negative component. So, it is going to be minus sine of theta times z.

You can already see that, if I take the dot product here,  $\vec{r} \cdot \hat{\theta}$ , this is 0, this gives you sine theta cos theta sine theta cos theta cosine square phi plus sine square phi minus sine theta and cosine of theta. So, this is going to be 0. So, they are orthogonal to each other, phi unit vector, it is pretty much the same like in the cylindrical coordinates and its coordinates are going to be therefore, minus sine of phi x plus cosine of phi y. These are the three unit vectors in cylindrical coordinates.

(Refer Slide Time: 07:19)

$\vec{r} = r \hat{r}$   
 $r \rightarrow r + dr$   
 $\theta \rightarrow \theta + d\theta$   
 $\phi \rightarrow \phi + d\phi$

$d\vec{r} = d(r \hat{r}) = dr \hat{r} + r(d\hat{r})$   
 $d\hat{r} = d\theta \hat{\theta} + \sin\theta d\phi \hat{\phi}$

$\hat{r}$  changes both due to change in  $\theta$  &  $\phi$   
 $\hat{r} = \sin\theta \cos\phi \hat{x} + \sin\theta \sin\phi \hat{y} + \cos\theta \hat{z}$

$d\hat{r} = \cos\theta \cos\phi d\theta \hat{x} + \cos\theta \sin\phi d\theta \hat{y} - \sin\theta \hat{z} d\theta + \sin\theta (-\sin\phi) d\phi \hat{x} + \sin\theta \cos\phi d\phi \hat{y}$

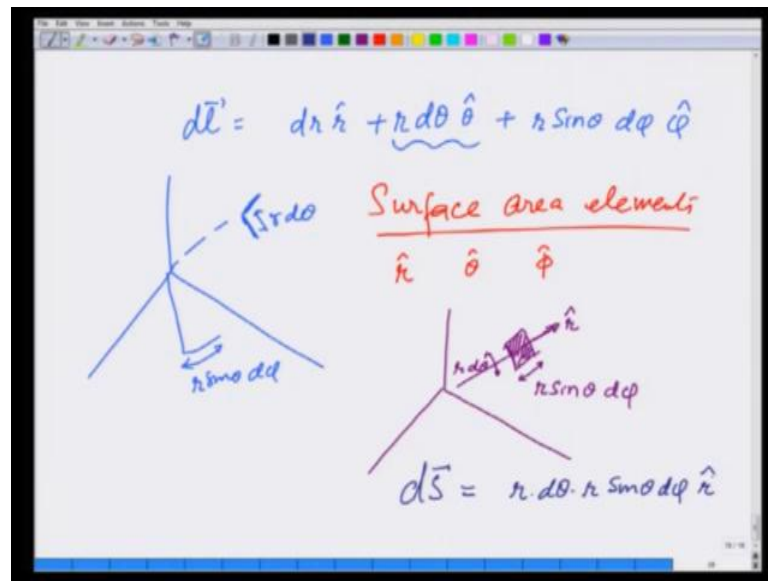

How about line element? First the position vector, position vector  $r$  is nothing but  $r$  unit vector  $\hat{r}$ ; that is the position vector in spherical coordinates. If I am going from one point to the other, I am changing  $r$  to  $r + dr$ , I am changing  $\theta$  to that plus  $d\theta$  and I am changing  $\phi$  to  $\phi + d\phi$ . So,  $dr$  is going to be nothing but  $d$  of  $r$  unit vector  $\hat{r}$  and I said earlier, these are not fixed. So, this is going to be  $dr$  in unit vector  $\hat{r}$  direction plus  $r$  times change in the  $\hat{r}$  unit vector,  $\hat{r}$  unit vector change comes both  $\hat{r}$  unit vector changes, both due to change in  $\theta$  and  $\phi$ .

Remember, what is the  $\hat{r}$  unit vector,  $\hat{r}$  unit vector is nothing but  $\sin\theta \cos\phi \hat{x} + \sin\theta \sin\phi \hat{y} + \cos\theta \hat{z}$ . Therefore,  $d\hat{r}$  unit vector, I can write as  $\cos\theta \cos\phi d\theta \hat{x} + \sin\theta \cos\phi d\theta \hat{y} + \sin\theta \sin\phi d\theta \hat{z} - \sin\theta \sin\phi d\phi \hat{x} + \sin\theta \cos\phi d\phi \hat{y} - \cos\theta d\theta \hat{z}$ . This is  $d\theta$  plus this change which is  $d\phi$   $\hat{\theta}$  unit vector, look at the terms, this one which is  $\hat{\theta}$  and this one.

If I take  $\sin\theta$  out, this becomes  $\cos\phi \hat{x} + \sin\phi \hat{y}$  and this should be  $\hat{\theta}$  and look at this term encircled in green. And here, if I take  $d\theta$  common, I get  $\cos\theta \cos\phi \hat{x} + \sin\theta \sin\phi \hat{y} - \cos\theta \hat{z}$  and what is this unit vector, this is  $\hat{\phi}$  unit vector. So, I can write this green thing, let me go here, I can write these green things combined together as  $d\theta \hat{\theta}$ .

In  $\theta$  direction and the blue things this one and this one, if I take  $d\phi$  and  $\sin\theta$  out, you left with  $-\sin\phi \hat{x} + \cos\phi \hat{y}$  which is  $\hat{\phi}$  unit vector. So, I can write this as  $d\phi \hat{\phi}$  unit vector put these things here.

(Refer Slide Time: 11:33)

So, what is the line element that I get? I get the line element  $d\vec{l}$  is equal to  $dr$  in  $r$  direction plus  $d\theta$  times  $r$  in  $\theta$  direction plus  $r \sin\theta d\phi$  in  $\phi$  direction. That makes perfect sense, because if I look at the coordinate system, if I move in  $r$  direction, this distance is  $dr$ , if I change  $\theta$ , this distance becomes  $r d\theta$ . So, that is this line element and if I change  $\phi$ , the distance I cover in  $\phi$  is going to be  $r \sin\theta d\phi$ . So, this is a line element.

Next let us look at surface elements, surface area elements perpendicular to  $r$  perpendicular to  $\theta$  and perpendicular to  $\phi$  let us look at perpendicular to  $r$  first. This element is going to look something like this, where this distance, this is unit vector  $\hat{r}$  is perpendicular to  $r$  and this distance is going to be distance moved in the  $x y$  plane. So, this is going to be  $r \sin\theta d\phi$  and this distance is going to be due to change in  $\theta$ . So, this is going to be  $r d\theta$ . So, the surface element, I can write in this form is  $d\vec{s}$  is equal to  $r d\theta$  times  $r \sin\theta d\phi$  in  $r$  direction, let us go to the next page.

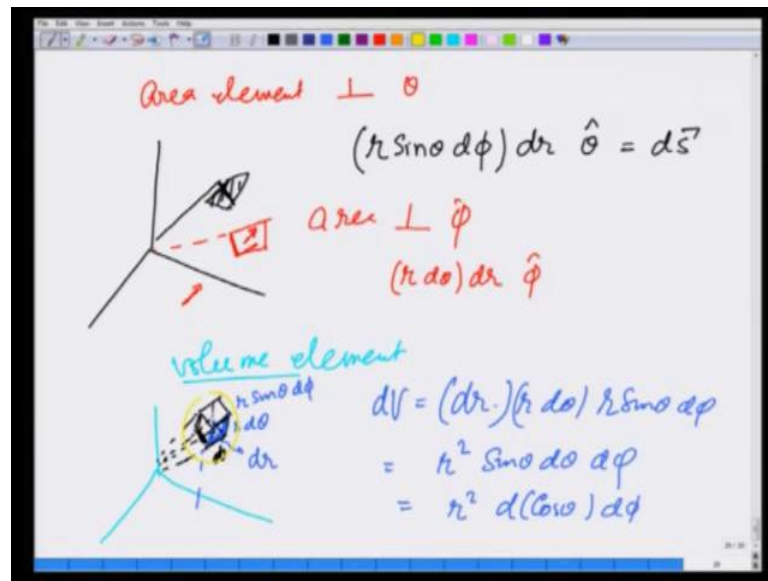

(Refer Slide Time: 13:30)

$$d\vec{S} = r^2 \sin\theta \, d\theta \, d\phi \, \hat{s}$$
$$0 \leq \theta \leq \pi \quad \& \quad 0 \leq \phi \leq 2\pi$$
$$= r^2 \, d(\cos\theta) \, d\phi$$
$$-1 \leq \cos\theta \leq 1$$
$$S = \int |d\vec{S}| = R^2 \int_{-1}^1 d(\cos\theta) \int_0^{2\pi} d\phi = 4\pi R^2$$

So,  $dS$  in  $r$  direction is  $r^2 \sin\theta$ , let me see, if I wrote  $d\theta$  back there is a  $d\theta$  here. So,  $r^2 \sin\theta \, d\theta \, d\phi$  and it is in  $S$  direction, where  $\theta$  varies from 0 to  $\pi$  and  $\phi$  varies from 0 to  $2\pi$ . Sometimes, this is also written as  $r^2 \, d(\cos\theta) \, d\phi$ , where  $d(\cos\theta)$  is integral over, you know the now I can take  $\cos\theta$  as the variable.

So,  $\cos\theta$  varies from minus 1 to 1, very easy to see that this is correct is, if I take a sphere of radius  $R$ , centre dot the origin, an element all area elements are perpendicular to  $S$ , because area is perpendicular to the radius. So, the total area is going to be integral magnitude of  $dS$  in the  $r$  direction which is going to be  $r$  is fixed, so  $R^2 \, d(\cos\theta)$  from minus 1 to 1  $d\phi$  from 0 to  $2\pi$  and that comes out to be  $4\pi R^2$ .

(Refer Slide Time: 14:55)

How about area element perpendicular to theta, let us look at that, if I am taking an area element perpendicular to theta, the distances covered are going to be in the r direction and in phi direction. In the phi direction, the distance cover is going to be r sine theta d phi, in the r direction, distance covered is going to be d r and this is going to be area element in S direction.

And area element perpendicular to phi; that is going to be here, perpendicular to phi and that is going to be again using a coordinate systems in r theta and phi will have a length element perpendicular to phi in theta direction, which is going to be r d theta. So, here will be r d theta and 1 in r direction and this unit vector is in the phi direction. So, r d theta times d r in phi direction.

How about the volume element? Let me first make one volume element and you will see, what it looks like, here in phi direction. So, this is in the r direction, this distance this is like projecting like this on to the centre. So, this distance shown by green or shown by red is d r. This distance is moving in theta direction is r d theta and the distance perpendicular to both is going to be r sine theta d phi.

So, these three are the small distances or small height, length and width of the volume element and therefore, the volume element is nothing but d r times r d theta times r sine theta d phi, which is equal to r square sine theta d theta, d phi is sometime also written as r square d cosine of theta d phi. To understand this figure, you have to imagine a bit or

look at a corner of the room, and see how you can you know think of that as the origin and how you can think of theta phi an r direction.

So, this is the three line elements area elements and volume elements in it is spherical coordinates. Using these one can derive expressions for curl by the definition of curl, divergence by the definition of divergence in these coordinate systems also. So, we have derived in the 2 lectures, the line elements, area elements and volume elements in Cartesian, cylindrical and spherical coordinate systems. Using these and using the Stokes theorem and divergence theorem or their definition, we can derive the expressions for the gradient divergence and curl also in these coordinate systems.
