Electrostatic potential due to a charge distribution – I a line charge of finite length

(Refer Slide Time: 00:11)

We have seen that the electrostatic potential due to a charge distribution is given as, if there is a charge distribution at r prime and I am calculating potential at vector r . Then the electrostatic potential V r is given as 1 over 4π Epsilon 0 , integration ρ r prime over r minus r prime d v prime, where d v prime indicate that, I am integrating over the r prime variable or over this volume, where the charge distribution is non-zero.

What we will do in this lecture is, use this to calculate potentials for two or three charge distributions. The examples I am going to take r going to be 1 a linear charge of charge density λ per unit length. A ring of charge of radius r , again carrying charge λ per unit length, this can be easily generalized to a disc of charge, which we did earlier in the case of electric field or force on a charge q . But, I am going to use it this time to calculate the potential due to a uniformly charge shell, a spherical shell carrying σ charge per unit area.

(Refer Slide Time: 01:54)

$$V(\vec{r}) = \int_{-L/2}^{L/2} \frac{\lambda dy'}{4\pi\epsilon_0 |\vec{r} - y'\hat{j}|}$$
$$* V(x, y, z) = \frac{\lambda}{4\pi\epsilon_0} \int_{-L/2}^{L/2} \frac{dy}{\sqrt{x^2 + z^2 + (y - y')^2}}$$

$x^2 + z^2 = \rho^2$

So, let us begin with the line charge and let us say, this is given at the origin with the center at the origin. The length is from minus L by 2 to L by 2 . And now, you see the advantage of using potential to calculate electric field later, because in the potential, I do not have to worry about any components. All I have to do is, if I calculate the potential due to this small charge λdy , then all I have to do is, calculate λdy over $4\pi\epsilon_0$ and the distance of that point from r is going to be r minus y , y unit vector.

And this integrate and y varying from minus L by 2 to L by 2 , no components nothing just one calculation. So, let us just do that. So, this is going to be integral. So, this is V at r or I can write this as V x y and z is equal to λ over $4\pi\epsilon_0$ comes out and I have minus L by 2 to L by 2 , the charge is sitting on the y axis x y . So, x and z components of the charges are 0 , and therefore I have dy over square root of x square plus z square plus I am calculating it at some point y .

So, I should just change the notation a bit, I will put a prime to indicate as I have been doing to show that it is a y prime over which I am integrating. So, I am calculating field the potential at y , y minus y prime square that is it, that is the integral that we are going to do.

(Refer Slide Time: 04:08)

The image shows a whiteboard with the following handwritten work:

$$V(x, y, z) = \frac{\lambda}{4\pi\epsilon_0} \int_{-L/2}^{L/2} \frac{dy'}{\sqrt{\rho^2 + (y-y')^2}}$$

$$y - y' = \rho \tan\theta$$

$$\ominus dy' = \rho \sec^2\theta d\theta$$

$$\theta_1 = \tan^{-1}\left(\frac{y+L/2}{\rho}\right) \text{ to } \theta_2 = \tan^{-1}\left(\frac{y-L/2}{\rho}\right)$$

$$V(x, y, z) = \frac{\lambda}{4\pi\epsilon_0} \int_{\theta_2}^{\theta_1} \frac{\rho \sec^2\theta d\theta}{\rho \sec\theta}$$

The final integral shows the cancellation of ρ and one $\sec\theta$ term, leaving $\int \sec\theta d\theta$.

Let us now to do the integral, let us take x square plus z square to be some ρ square. So, V x y z is given as λ over $4\pi\epsilon_0$, integration dy' over square root of ρ square plus y minus y prime square and y prime varies from $-L/2$ to $L/2$. To perform the integral, let me write y minus y prime equals ρ tangent of θ , so that I have dy' equals ρ secant square θ $d\theta$ and the limits are from θ_1 equals $\tan^{-1}(y + L/2$ over $\rho)$ to θ_2 equals $\tan^{-1}(y - L/2$ over $\rho)$.

So, that the integral now can be written as V x y z equals λ over $4\pi\epsilon_0$. This minus sign changes the limits, the other way, so I am going to have θ_2 to θ_1 ρ secant square θ $d\theta$ over ρ secant θ and this ρ cancels and one of this secant θ is cancelled and I am left with the secant θ here.

(Refer Slide Time: 05:54)

$$V(x, y, z) = \frac{\lambda}{4\pi\epsilon_0} \int_{\theta_2}^{\theta_1} \sec\theta \, d\theta$$

$$= \frac{\lambda}{4\pi\epsilon_0} \ln \left| \frac{\sec\theta_1 + \tan\theta_1}{\sec\theta_2 + \tan\theta_2} \right|$$

$L \rightarrow \infty$ or $y \rightarrow 0$

$L \rightarrow \infty \quad \theta_1 = \tan^{-1} \left(\frac{y+L/2}{\rho} \right)$
 $\tan\theta_1 = \left(\frac{y+L/2}{\rho} \right), \quad \tan\theta_2 = \frac{y-L/2}{\rho}$

And therefore, the potential then becomes $V \times y \times z$ equals λ over $4 \pi \epsilon_0$ θ_2 to θ_1 secant θ $d \theta$, which is nothing but λ over $4 \pi \epsilon_0$, \ln of $\sec \theta_1 + \tan \theta_1$ divided by $\sec \theta_2 + \tan \theta_2$; that is the answer. Now, our particular interests, either you take limit L will go to infinity or y going to 0. Let us take the limit L going to infinity. In that case, θ_1 which was equal to $\tan^{-1} (y + L/2 \text{ over } \rho)$ becomes $\tan \theta_1$ equals $y + L/2$ over ρ and $\tan \theta_2$ becomes $y - L/2$ over ρ .

(Refer Slide Time: 07:16)

$$V(x, y, z) = \frac{\lambda}{4\pi\epsilon_0} \ln \left[\frac{\sec\theta_1 + \tan\theta_1}{\sec\theta_2 + \tan\theta_2} \right]$$

~~$= \frac{\lambda}{4\pi\epsilon_0} \ln \left[\frac{\sqrt{\rho^2 + (y+L/2)^2} + \frac{y+L/2}{\rho}}{\sqrt{\rho^2 + (y-L/2)^2} + \frac{y-L/2}{\rho}} \right]$~~

$$\tan\theta_1 = \frac{y+L/2}{\rho} \quad \tan\theta_2 = \frac{y-L/2}{\rho}$$

$$\sec\theta_1 = \frac{\sqrt{\rho^2 + (y+L/2)^2}}{\rho} \quad \sec\theta_2 = \frac{\sqrt{\rho^2 + (y-L/2)^2}}{\rho}$$

This gives $V(x, y, z)$ as $\frac{\lambda}{4\pi\epsilon_0} \log \sec \theta_1 + \tan \theta_1$ over $\sec \theta_2 + \tan \theta_2$ equal to $\frac{\lambda}{4\pi\epsilon_0} \log$ of $\sec \theta_1$ will be 1 over $\cos \theta_1$ which becomes 1 over. Let us check that \tan of θ_1 is $y + L/2$ over ρ , so this will become ρ over $\sqrt{L/2$ square plus ρ square plus $y + L/2$ whole square.

We have $\tan \theta_1$ is equal to $y + L/2$ over ρ \tan of θ_2 equals $y - L/2$ over ρ . And therefore, $\sec \theta_1$ is equal to $\sqrt{\rho^2 + (y + L/2)^2}$ divided by ρ $\tan \theta_2$ is equal to $\sqrt{\rho^2 + (y - L/2)^2}$ over ρ , this is $\sec \theta_2$.

(Refer Slide Time: 09:06)

The image shows a whiteboard with the following handwritten derivation:

$$L \rightarrow \infty \quad \frac{L \pm y}{2} \rightarrow \frac{L}{2}$$

$$V(x, y, z) = \frac{\lambda}{4\pi\epsilon_0} \ln \left[\frac{4L^2}{4\rho^2} + 1 \right]$$

$$= \frac{\lambda}{4\pi\epsilon_0} \left[\ln \left(\frac{L^2}{\rho^2} \right) - \ln \rho^2 \right]$$

$$= \frac{\lambda}{4\pi\epsilon_0} \times -2 \ln \rho = -\frac{\lambda}{2\pi\epsilon_0} \ln \rho$$

You work all this out and in the limit of L tending to infinity, so that 1 plus or minus L by 2 plus or minus y can be taken as $L/2$, you get $V(x, y, z)$ as equal to $\frac{\lambda}{4\pi\epsilon_0} \log$ of $4L^2$ over ρ^2 plus 1 , 4 is not on top, 4 is a bottom. It comes out to be this, which I can write as equals since L is much, much, much greater than 1 , L^2 over $4\rho^2$ is going to be much, much, much greater than 1 .

So, I can write all that as $V(x, y, z)$ equals $\frac{\lambda}{4\pi\epsilon_0} \log L^2$ by 4 minus $\log \rho^2$ as L will tell to infinity this fellow goes to infinity. However, in calculating potential, I can always neglect that infinity part. So, I can write this as $\frac{\lambda}{4\pi\epsilon_0} \log L^2$ minus $2 \log \rho$, which is $-\frac{\lambda}{2\pi\epsilon_0} \ln \rho$.

$\pi \epsilon_0 \log \rho$. That is the answer for L tend to infinity, this match as well with congenital expression and that you know for an infinitely long wire.
