Lecture - 39
Equation for the Vector Potential in terms of current density

We have been discussing vector field $\vec{A}(\vec{r})$ that is related to magnetic field $\vec{B}(\vec{r})$ to Curl equation.

(Refer Slide Time: 00:12)

What we want to do in this lecture is, develop an equation for the vector field $\vec{A}(\vec{r})$, directly in terms of the current density $\vec{j}(\vec{r})$. Something similar to Poisson's equation for $V(\vec{r})$, the electro static potential in terms of $\rho(\vec{r})$. And then if I can calculate \vec{A} directly in an easier way then I calculate \vec{B} and then take its curl to get \vec{B} that will be a good way of calculating \vec{B} for a given current distributions. So, that is the motivation.

(Refer Slide Time: 01:37)

The image shows a whiteboard with the following handwritten text:

$$\vec{\nabla} \times \vec{A} = \vec{B}(\vec{r})$$
$$\vec{\nabla} \times (\vec{\nabla} \times \vec{A}) = \vec{\nabla} \times \vec{B} = \mu_0 \vec{j}(\vec{r})$$

↓

$$\vec{\nabla}(\vec{\nabla} \cdot \vec{A}) - \nabla^2 \vec{A} = \mu_0 \vec{j}(\vec{r})$$

Freedom in choosing $\vec{A} \leftrightarrow \vec{\nabla} \cdot \vec{A} = 0$

$$\nabla^2 \vec{A} = -\mu_0 \vec{j}(\vec{r})$$

To develop this equation, we start with the equation, curl of A is B of r and take curl again on both sides. The curl of A is equal to curl of B, for curl of B, I know in terms of the current density, which is nothing but mu naught j of r. And the left hand side, I know from vector identity it is nothing but gradient of divergence of A minus Laplacian of vector A.

By taking Laplacian of vector A, one means that you are taking Laplacian of each component of A and this is equal to mu naught j of r. Now, recall from my earlier lectures that there is a freedom in choosing A in that, we can add a gradient to it and therefore, I can choose A in such a way that divergence of A is 0. If I do that, then I am left with the equation Laplacian of A is equal to minus mu naught j of r; that is the equation, Poisson's equation for vector field, let us understand what it means.

(Refer Slide Time: 03:21)

$$\nabla^2 \vec{A} = -\mu_0 \vec{J}(\vec{r}) \quad \nabla \cdot \vec{A} = 0$$

$$\nabla^2 \phi(\vec{r}) = -\frac{\rho(\vec{r})}{\epsilon_0}$$

$$\begin{cases} \nabla^2 A_x(\vec{r}) = -\mu_0 j_x(\vec{r}) \\ \nabla^2 A_y(\vec{r}) = -\mu_0 j_y(\vec{r}) \\ \nabla^2 A_z(\vec{r}) = -\mu_0 j_z(\vec{r}) \end{cases}$$

In free space

$$A_x(\vec{r}) = \frac{\mu_0}{4\pi} \int \frac{j_x(\vec{r}')}{|\vec{r} - \vec{r}'|} dV'$$

$$A_y(\vec{r}) = \frac{\mu_0}{4\pi} \int \frac{j_y(\vec{r}')}{|\vec{r} - \vec{r}'|} dV'$$

$$A_z(\vec{r}) = \frac{\mu_0}{4\pi} \int \frac{j_z(\vec{r}')}{|\vec{r} - \vec{r}'|} dV'$$

The equation we have is del square of A is equal to mu naught minus mu naught j of r, under the condition that divergence of A is 0 and keep in mind, that this is all for a steady state current. What it means is that each component del square A x is equal to minus mu naught j x r, del square A y at r is equal to minus mu naught j y at r. And finally, del square A z of r is equal to minus mu 0 j z of r.

All these equations are absolutely similar to this Poisson's equation, phi of r is equal to minus rho of r over Epsilon 0, all we are doing is 1 over Epsilon 0 is being replaced by mu 0 and rho is being replaced by j x, phi is being replaced by A x and y and z component. Therefore, the equation has the same solution or similar solution as for the Poisson's equation.

So, in free space, we already know the solution for the electrostatic potential, I have been using V r, so I should be using V r. In free space therefore, A x at r is going to be equal to mu 0 over 4 pi integral of j x r prime over r minus r prime d v prime. Similarly, A y at r is going to be mu naught over 4 pi integral j y at r prime over r minus r prime d v prime. And similarly equation for A z at r is equal to mu naught over 4 pi integral j z r prime over r minus r prime d v prime.

(Refer Slide Time: 05:53)

$$\vec{A}(\vec{r}) = \frac{\mu_0}{4\pi} \int \frac{\vec{J}(\vec{r}')}{|\vec{r} - \vec{r}'|} dV'$$

Example 1 :

$$\int \vec{J}(s) \cdot d\vec{s} = I$$

$$\vec{J}(s) = \frac{I \delta(s)}{2\pi s} \hat{z}$$

$$\int \vec{J} \cdot d\vec{s} = \int \frac{I \delta(s)}{2\pi s} \cdot 2\pi s ds \hat{z} \cdot \hat{z} = I$$

To write it altogether, what I have is then A vector at r is given as mu naught over 4 pi integral j vector r at r prime over r minus r prime d v prime; that is the equation for vector potential. Very similar to the equation for electrostatic potential except that now, I have three components, because this is the vector potential. Once, I know the current density I can calculate from this the vector potential and taking its curl, I can always get my magnetic field.

Let us now solve a few examples, as example 1; I am going to take current I, going in a wire along the Z axis. So, this is the well known example, we have been solving so far and I want to calculate for the vector potential directly. Let us write the current density for this, you see current is going only at S equals 0 and I know by definition, current density rho d s should be equal to I.

Current density is going in the Z direction, its magnitude is I, it is only at S equals 0, where the density becomes infinite and to normalize, I am going to do it divide by 2 pi S and that is it; that is the current density, let us check, if this is correct. If I take this area across the wire, j dot d s gives me I delta s prime over 2 pi S prime, area is going to be 2 pi S prime d s prime Z dot Z, because area is in the Z direction integral.

2 pi S prime cancels with 2 pi s prime and integral over S prime gives me 1 and therefore, this is equal to I. So, I have got the correct current density; let us then directly use this to calculate the vector potential.

(Refer Slide Time: 08:19)

The image shows a handwritten derivation on a whiteboard. On the left, a vertical line represents an infinite wire along the z-axis, extending from $-\infty$ to ∞ . A point \vec{r} is shown at a distance Z from the origin along the z-axis. The derivation starts with the Biot-Savart law for the vector potential:

$$\vec{A}(\vec{r}) = \frac{\mu_0}{4\pi} \int \frac{\vec{j}(\vec{r}')}{|\vec{r} - \vec{r}'|} dV'$$

Since the current is along the z-axis, $\vec{j}(\vec{r}') = j \hat{z} \delta(s') \delta(z' - z)$. The volume element $dV' = s' ds' dz'$. The distance $|\vec{r} - \vec{r}'| = \sqrt{(s - s')^2 + z'^2}$. The derivation then simplifies to:

$$= \frac{\mu_0}{4\pi} \int \frac{I/2\pi s' \delta(s') \hat{z} \cdot 2\pi s' ds' dz'}{\sqrt{(s - s')^2 + z'^2}}$$

$$= \frac{\mu_0 I}{4\pi} \hat{z} \int_{-\infty}^{\infty} \frac{dz'}{\sqrt{s^2 + z'^2}}$$

Finally, the substitution $z' = s \tan \theta$ is used, leading to an integral over θ from $-\pi/2$ to $\pi/2$:

$$\frac{\mu_0 I}{4\pi} \hat{z} \int_{-\pi/2}^{\pi/2} \frac{s \sec^2 \theta d\theta}{s \sec \theta}$$

A vector potential A_r is equal to μ_0 over 4π integral j_r prime over r minus r prime dV prime. Remember this is a current carrying wire going from minus infinity to plus infinity. This is equal to μ_0 over 4π integral I over $2\pi s$ prime, because this is at s prime, δs prime, this is a vector in Z direction, dV is going to be $2\pi s$ prime ds prime dZ prime over.

Since, this is at infinite wire at any Z , the answer for A is going to be the same, therefore I may as well calculate it at Z equal to 0. So, this is going to be square root of S vector minus S prime vector square plus Z prime square. Since, S prime goes to 0, this becomes $\mu_0 I$ over 4π in Z direction and you can see this $2\pi s$ prime and $2\pi s$ prime cancel, this δs prime with δs prime here gives me s prime equal to 0. So, I am left with integral minus infinity to infinity dZ prime over square root of S square plus Z prime square.

Let us do this integral, I do this integral by taking Z prime equals S tangent θ and this gives me $\mu_0 I$ over $4\pi Z$ integral S secant square θ , $d\theta$ over S sec θ minus $\pi/2$ to $\pi/2$. This S cancels and you can see this is an integral of secant θ , $d\theta$ will give me \log tangent plus secant θ and that blows up in this case. So, I have to actually do this calculation by taking a long wire going from minus L to L and then taking the limit L going to infinity and that will give me the S dependence. So, let us do that properly.

(Refer Slide Time: 10:59)

The image shows a handwritten derivation of the magnetic vector potential $\vec{A}(s, z=0)$ for a long wire of length $2L$ carrying current I . The wire is located along the z' axis from $-L$ to L . The observation point is at $(s, z=0)$. The derivation proceeds as follows:

$$\vec{A}(s, z=0) = \frac{\mu_0 I}{4\pi} \int_{-L}^L \frac{dz'}{\sqrt{s^2 + z'^2}} \hat{z}$$

$$= \frac{\mu_0 I}{4\pi} \times 2 \int_0^L \frac{dz'}{\sqrt{s^2 + z'^2}} \hat{z}$$

$$= \frac{\mu_0 I}{2\pi} \hat{z} \int_0^{\tan^{-1}(L/s)} \frac{s \sec^2 \theta}{s \sec \theta} d\theta$$

$$= \frac{\mu_0 I}{2\pi} \hat{z} \ln |\sec \theta + \tan \theta| \Big|_0^{\tan^{-1}(L/s)}$$

Therefore I am going to write A at S, Z equal to 0 , because now I am taking a long wire extending from minus L to L and I am calculating A at Z equal to 0 . This is going to be equal to $\mu_0 I$ over 4π integral minus L to L dZ prime over square root of S square plus Z prime square. This is in the Z direction, which I can write as $\mu_0 I$ over 4π times 2 , because the integral is even in Z prime, I can make it from 0 to L , dZ prime over square root of S square plus Z prime square in the Z direction.

So, I get this to be equal to $\mu_0 I$ over 2π , in the Z direction integral again making substitution Z prime equals S tangent θ I will get S secant square θ over S secant θ , $d\theta$, tangent θ is going to vary from 0 to $\tan^{-1} L$ over S . So, now let us do some cancellations again S cancels the secant θ square cancels here and I get secant θ .

And therefore, my answer comes out to be $\mu_0 I$ over 2π in the Z direction \ln of secant θ plus tangent θ 0 and $\tan^{-1} L$ over S , which I can simplify to at 0 tangent θ is 0 , secant θ is 1 , so that gives me 0 .

(Refer Slide Time: 13:06)

$$\begin{aligned} \vec{A}(s, z=0) &= \frac{\mu_0 I}{2\pi} \hat{z} \ln \left| \frac{L}{s} + \sqrt{1 + \frac{L^2}{s^2}} \right| \\ L \rightarrow \infty &= \frac{\mu_0 I}{2\pi} \hat{z} \ln \left| \frac{2L}{s} \right| \\ &= \frac{\mu_0 I}{2\pi} \hat{z} \ln 2L - \frac{\mu_0 I}{2\pi} \ln s \hat{z} \\ \vec{A}(s, z) &= -\frac{\mu_0 I}{2\pi} \ln s \hat{z} \end{aligned}$$

And so this comes out to be A at s z equal to 0, comes out to be mu naught I over 2 pi in Z direction log of tan inverse L over S tangent of that gives me L over S plus square root of 1 plus L square over S square is the secant theta. For L going to infinity, this can be written as mu 0, I over 2 pi, Z log of L over S plus L over S again, because I can ignore that 1.

So, I will erase this and write this as 2 L over S, which is equal to mu naught I over 2 pi Z log of 2 L minus mu naught I over 2 pi log of S Z. This part goes to infinity as L goes to infinity. So, I can ignore this, I mean this is just addition of infinity. So, the S dependence actually comes out to be A S, Z it does not depend on. So, I may write, may not write it is equal to mu naught I over 2 pi log S in the Z direction indeed the answer we had obtained earlier.

(Refer Slide Time: 14:56)

Let us do one more example and that is going to be that of a sheet of current for which we have already calculated magnetic field and we also calculated A , but now we want to do it directly. This is X direction, this is Y direction and to remind yourself, you may want to look up the lectures we have done earlier. This is Z direction and this is carrying a surface current K , which is K in the Y direction.

So, this carry is a surface current K is equal to K in the Y direction. The current density can therefore, be written as K , the area across which it is going is the $Y Z$ plane. So, in the Z plane, it is confined to Z equal to 0 . So, I can write $K \delta Z$ in the Y direction. How do we check this, let me take a cross section across which the current is flowing. So, if I do $\vec{j} \cdot d\vec{s}$ across this cross section, I am going to get if this length is L , $L dz K \delta Z y$ which gives me y is the direction of area also.

So, this gives me KL , which is the current indeed passing through length L of the sheet. So, our \vec{j} is correct, therefore, A the vector potential A at any point \vec{r} is going to be $\mu_0 / 4\pi \int \vec{j}(\vec{r}') / |\vec{r} - \vec{r}'| dv'$, which is equal to $\mu_0 / 4\pi \int K \delta Z' \hat{y} / |\vec{r} - \vec{r}'| dv'$.

Now, let us see this is a plane sheet. So, the answer should not really depend on with which x , which y , am I calculating it at, because it is invariant, it does not matter, which x which y , because in xy plane, this is infinite extent. So, I may as well calculate A at x

equal to 0, which maybe the same as any at any other x, it just makes my life little easy, y equal to 0 and z, which will be equal to mu naught over 4 pi integral k delta Z prime, it is in Y direction divided by r minus r prime.

Since, I am calculating it at x and y equal to 0 is going to be only x prime square plus y prime square plus z minus Z prime square d x prime, d y prime, d Z prime; that is the expression, let us write this again.

(Refer Slide Time: 18:28)

The image shows a handwritten derivation on a whiteboard. On the left, there is a 3D coordinate system with x, y, and z axes. A circular current sheet is shown in the xy-plane, with a current density vector \hat{y} pointing in the positive y-direction. The vector potential \vec{A} is shown to be in the y-direction. The derivation proceeds as follows:

$$\vec{A}(0,0,z) = \frac{\mu_0}{4\pi} \int \frac{K \delta(z') \hat{y} dx' dy' dz'}{\sqrt{x'^2 + y'^2 + (z-z')^2}}$$

$$= \frac{\mu_0 K \hat{y}}{4\pi} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{dx' dy'}{\sqrt{x'^2 + y'^2 + z^2}}$$

$$\frac{dx' dy'}{x'^2 + y'^2} = \frac{2\pi s' ds'}{s'^2} = \frac{\mu_0 K \hat{y}}{4\pi \cdot 2} \int \frac{2\pi s' ds'}{\sqrt{s'^2 + z^2}}$$

$$= \frac{\mu_0 K \hat{y}}{2} \int_0^{\infty} \frac{s' ds'}{\sqrt{s'^2 + z^2}}$$

So, I am calculating due to this sheet of charge, which is carrying the surface current in direction Y. We have calculated A 0, 0 it does not matter any x, y with the same answer at Z is equal to mu naught over 4 pi integral K delta Z prime, it is in y direction d x prime, d y prime, d Z prime over square root of x prime square plus y prime square plus z minus Z prime square.

Now, the integral over Z prime because of delta Z prime gives me Z prime equals 0 and therefore, this becomes equal to mu naught K comes out Y direction comes out. It is a fixed direction over 4 pi integral of d x prime d y prime over square root of x prime square plus y prime square plus z square, both x and y going from 0 or minus infinity to plus infinity minus infinity to plus infinity.

I can make this integral very easy, if I realize that this actually is an area integral. So, I can convert this area integral into in terms of the cylindrical coordinates or planar polar

coordinates, whereby dx' , dy' , I can write as $2\pi S' ds'$, $x'^2 + y'^2 = s'^2$. So, instead of taking this $dx' dy'$, let me make in a different color.

Like this, since this is an integral which is symmetric, I am actually taking this area and integrating over it is the same thing as long as I covered the entire area. And therefore, I can write this expression as equal to $\mu_0 K y$ over 4π integral 0 to ∞ $2\pi S' ds'$ over square root of $S'^2 + z^2$ this 2π cancels with this I get 2 .

And therefore, the expression becomes $\mu_0 K y$ over 2 integral 0 to ∞ $s' ds'$ over $s'^2 + z^2$ root and this is very easy to calculate, let us do that.

(Refer Slide Time: 21:23)

The image shows a whiteboard with the following handwritten mathematical steps:

$$\vec{A}(z) = \frac{\mu_0 K \hat{y}}{2} \int_0^\infty \frac{s' ds'}{\sqrt{z^2 + s'^2}}$$

$$z^2 + s'^2 = Y^2$$

$$Y dY = s' ds'$$

$$\vec{A}(z) = \frac{\mu_0 K \hat{y}}{2} \int_{|z|}^\infty \frac{Y dY}{Y} = \frac{\mu_0 K \hat{y}}{2} Y \Big|_{|z|}^\infty$$

$$\vec{A}(z) = -\frac{\mu_0 K}{2} |z| \hat{y}$$

So, you have got in A at any point, but depends only on Z , x y does not matter is equal to $\mu_0 K$ in y direction over 2 integral 0 to ∞ $S' ds'$ over square root of $Z^2 + s'^2$. Let us take $Z^2 + S'^2$ to be Y^2 , so that $Y dY$ is equal to $S' ds'$. So, I get A_z is equal to $\mu_0 K$ over 2 Y integral modulus of z to ∞ $Y dY$ over Y . This Y cancels and I end up getting $\mu_0 K$ over 2 at mod Z an infinity.

Again, at infinity it is a constraint which I will ignore and therefore, the Z dependence of A finally, comes out to be A_z is equal to $\mu_0 K$ over 2 modulus Z with the minus sign in the Y direction, indeed the answer we had obtained earlier looking at b. So, you see I have given you two examples where we can calculate A directly from A current distribution, and now I can take it is curl and get my answer for B.
