**Lecture - 05**  
**Electric Field due to a Charged Distribution**

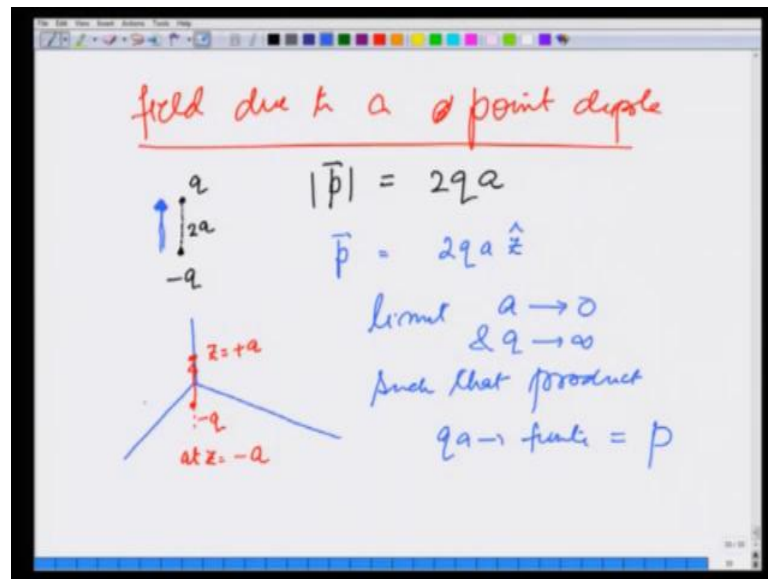

In the previous lectures, we have discussed the Electric Field due to Charges and Charge Distributions. In fact, while calculating forces on a given charge  $q$ , we had also calculated electric field due to a charge distribution, because if I take small  $q$  to be 1, it becomes the electric field. Let us do some more examples of calculating electric field in this lecture, I will do two examples here and both are important and will be used in the future.

(Refer Slide Time: 00:48)

I am going to calculate electric field due to example 1 a, an electric dipole and 2 due to a surface charge. In example 2, you will also learn a trick to deal with such cases. In both the cases, we will be doing some limiting processes. So, this is quite an instructive and important lecture.

(Refer Slide Time: 01:33)

To calculate the field due to a dipole, I am going to be more specific a point dipole what we are going to do is take the dipole to be made up of 2 charges minus  $q$  and plus  $q$  separated by distance  $2a$ . So, that the magnitude of dipole moment is given by  $2qa$ , and the direction of dipole moment is from negative to positive charge.

So,  $p$  is going to have a direction from negative to positive charge, if I take the dipole to be sitting at the origin and in the  $z$  direction, then I will take the charges minus  $q$  at minus  $a$  at  $z$  equals minus  $a$  and plus  $q$  to be sitting at  $z$  equals plus  $a$  and I can write the dipole moment  $p$  of this to be equal to  $2qa$  in the  $z$  direction. To make it a point dipole finally, what we are going to do is take limit  $a$  going to  $0$  and  $q$  going to infinity, such that product  $qa$  remains finite and equal to some  $p$  value that makes it a point dipole. So, let us calculate the field due to this point dipole.

(Refer Slide Time: 03:32)

The whiteboard contains a diagram on the left showing a vertical line with two red dots representing charges. A vector  $\vec{r}$  points from the origin to a point. Two other vectors are shown:  $(\vec{r} - a\hat{z})$  pointing to the top charge and  $(\vec{r} + a\hat{z})$  pointing to the bottom charge. To the right, the electric field is given as:

$$\vec{E}(\vec{r}) = \frac{1}{4\pi\epsilon_0} \left[ \frac{q(\vec{r} - a\hat{z})}{|\vec{r} - a\hat{z}|^3} - \frac{q(\vec{r} + a\hat{z})}{|\vec{r} + a\hat{z}|^3} \right]$$

Below this, the limit  $a \rightarrow 0$  is indicated. The modulus of  $\vec{r} + a\hat{z}$  is expanded as:

$$|\vec{r} + a\hat{z}| = \left( r^2 + a^2 + 2ar \cos\theta \right)^{1/2}$$

Finally, for  $a \rightarrow 0$  (where  $a \ll r$ ), the expression is approximated as:

$$a \rightarrow 0 \quad (a \ll r) \quad \approx r \left( 1 \pm \frac{2a}{r} \cos\theta \right)$$

I am going to make it again, this is my point dipole plus  $q$  sitting here minus  $q$  sitting here. So, the field at some vector  $r$  is going to be  $1$  over  $4\pi$  Epsilon  $0$   $q$  the positive charge gives me the field  $q$   $r$  minus  $a$  in the  $z$  direction. I will write a cube here and a vector  $r$  minus  $a$   $z$  on the top, there is a field due to the positive charge and that due to negative charge is going to be minus  $q$   $r$  plus  $a$   $z$  over  $r$  plus  $a$   $z$  cubed.

To make it more explicit, let me draw this point  $r$ , this is vector  $r$  minus  $a$   $z$  and the one from the bottom here is  $r$  plus  $a$   $z$  and we want to calculate this field and finally, take the limit  $q$  times  $a$  going to a finite number. Since, we are already assuming that we are going to take the limit  $a$  going to  $0$ , I can expand these two quantities in the denominator. So, let us write modulus of  $r$  plus  $a$   $z$ , I am going to include minus also right here which is going to be square root of  $r$  square plus  $a$  square plus  $2$   $a$   $r$  dot product of  $r$  unit vector with  $z$  unit vector which is going to be cosine theta raise to  $1$  half and for the minus sign it will be minus here.

Since, I am going to take  $a$  going to  $0$ , so  $a$  is much, much, much less than  $r$  we are going to neglect  $a$  square term and keep only this term. So, by Binomial theorem I can approximate this as  $r$   $1$  plus or minus  $2$   $a$  by  $r$  cosine theta raise to  $1$  half which is...

(Refer Slide Time: 06:13)

The image shows a whiteboard with handwritten mathematical derivations. At the top, the expression  $|\vec{r} \pm a\hat{z}|^3$  is equated to  $r^3 \left(1 \pm \frac{2a}{r} \cos\theta\right)^{3/2}$ . This is then approximated as  $r^3 \left(1 \pm \frac{3a}{r} \cos\theta\right)$ . To the left, a diagram shows a coordinate system with a red vector  $\vec{r}$  and a black vector  $a\hat{z}$  along the z-axis. The electric field expression is given as  $E(\vec{r}) = \frac{q}{4\pi\epsilon_0} \left[ \frac{(\vec{r}-a\hat{z})}{r^3 \left(1 - \frac{3a}{r} \cos\theta\right)} - \frac{(\vec{r}+a\hat{z})}{r^3 \left(1 + \frac{3a}{r} \cos\theta\right)} \right]$ . The terms  $\left(1 - \frac{3a}{r} \cos\theta\right)$  and  $\left(1 + \frac{3a}{r} \cos\theta\right)$  are circled in purple. The final simplified expression is  $E(\vec{r}) = \frac{q}{4\pi\epsilon_0 r^3} \left[ (\vec{r}-a\hat{z}) \left(1 + \frac{3a}{r} \cos\theta\right) - (\vec{r}+a\hat{z}) \left(1 - \frac{3a}{r} \cos\theta\right) \right]$ .

Thus we can write  $r$  plus or minus  $a$  cubed as  $r$  cubed  $1$  plus or minus  $2a$  over  $r$  cosine theta raise to  $3$  by  $2$  which by Binomial theorem is  $r$  cubed  $1$  plus or minus  $3a$  over  $r$  cosine theta. And therefore, the field due to this dipole sitting at the origin at a distance  $r$  is going to be given as  $E$   $r$  equals  $q$  over  $4\pi\epsilon_0$ . Inside I have vector  $\vec{r}$  minus  $a$   $\hat{z}$  divided by  $r$  cubed  $1$  minus  $3a$  over  $r$  cosine theta minus let me use a different colour  $r$  plus  $a$   $\hat{z}$  over  $r$  cubed  $1$  plus  $3a$  over  $r$  cosine of theta bracket closed.

Again I am going to use Binomial theorem and take the factors encircled in purple to the numerator and write this whole thing as  $E$   $r$  equals  $q$  over  $4\pi\epsilon_0$   $r$  cubed I am going to take out  $r$  cubed and inside, I am left with  $\vec{r}$  minus  $a$   $\hat{z}$  times  $1$  plus  $3a$  over  $r$  cosine of theta minus  $\vec{r}$  plus  $a$   $\hat{z}$  times  $1$  minus  $3a$  over  $r$  cosine of theta.

(Refer Slide Time: 08:41)

The whiteboard shows the following steps:

$$E(\vec{r}) = \frac{q}{4\pi\epsilon_0 r^3} \left[ \vec{r} + \frac{3a}{r} \vec{r} \cos\theta - a \hat{z} - \vec{r} + \frac{3a}{r} \vec{r} \cos\theta - a \hat{z} \right]$$

$$\frac{\vec{r}}{r} = \hat{r} \quad E(\vec{r}) = \frac{q}{4\pi\epsilon_0 r^3} \left[ 6a \hat{r} \cos\theta - 2a \hat{z} \right]$$

Limit  $a \rightarrow 0, q \rightarrow \infty, 2qa \rightarrow p$

$$= \frac{(2aq)}{4\pi\epsilon_0} \left[ (3 \cos\theta \hat{r}) - \hat{z} \right] = \vec{p}$$

$$\vec{p} = 2aq \hat{z}$$

$2aq \cdot 3 \times \cos\theta \hat{r}$      $\cos\theta = \hat{z} \cdot \hat{r}$   
 $= \{(2aq \hat{z}) \cdot \hat{r}\} \hat{r} \times 3 = 3(\vec{p} \cdot \hat{r}) \hat{r}$

I will again expand this keeping terms only up to first order in  $a$  and what I get is  $E_r$  is equal to  $q$  over  $4\pi\epsilon_0 r^3$   $r$  plus  $3a$  over  $r$ ,  $r$  vector cosine of  $\theta$  minus  $a$   $z$  minus  $r$  plus  $3a$  over  $r$ ,  $r$  vector cosine of  $\theta$ , this blue one is the second term minus  $a$   $z$  let me check if I am doing it correctly, ((Refer Time: 09:24)) yes this is indeed correct. And now, if I use the fact that  $r$  vector divide by  $r$  is unit vector  $\hat{r}$ , then I can write  $E_r$  as  $q$  over  $4\pi\epsilon_0 r^3$  and by the way here this term cancels, inside I get  $6a$   $r$  unit vector cosine of  $\theta$  minus  $2a$   $z$  which I can write as take  $2a$  out  $2a$   $q$  over  $4\pi\epsilon_0$   $3$  cosine of  $\theta$   $r$  unit vector minus  $z$ .

I now want to be more general and realize that  $p$  vector is equal to  $2aqz$  and therefore, the term  $2aq$  combined with the first term here is  $2aq$  times  $3$  cosine of  $\theta$ , cosine  $\theta$  is nothing but  $z$  dot  $r$   $r$  unit vector. So, I can write this as equal to  $2aqz$  dot  $r$  times unit vector  $\hat{r}$  multiplied by  $3$  which is nothing but  $3p$  dot  $r$ . Similarly,  $2aqz$  this whole term combined with  $z$  is nothing but  $p$  and remember I am taking the limit that I am working under is that  $a$  goes to  $0$  and  $q$  goes to infinity, such that  $2qa$  goes to  $p$ .

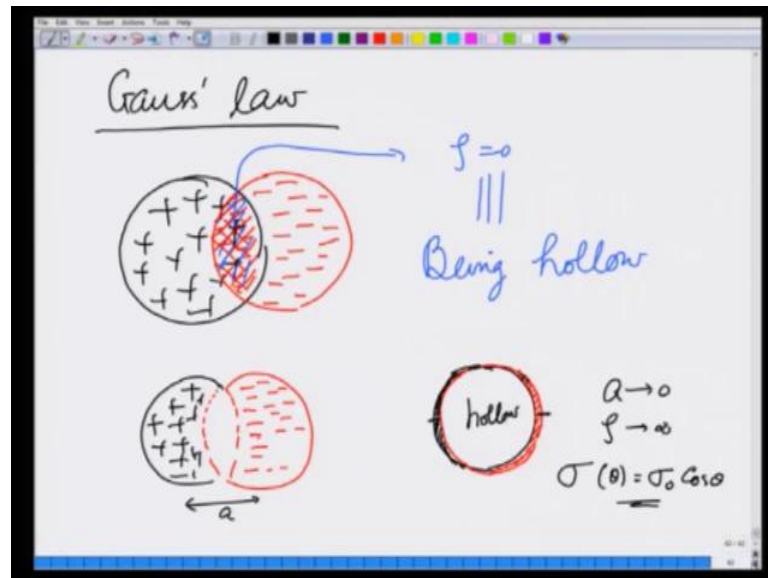

(Refer Slide Time: 12:00)

The image shows a handwritten derivation on a whiteboard. At the top, the electric field  $E(\vec{r})$  is given as  $\frac{3(\vec{p} \cdot \hat{r})\hat{r} - \vec{p}}{4\pi\epsilon_0 r^3}$ . Below this, it states "If the dipole is at  $\vec{r}'$ ". The next equation is  $E(\vec{r}) = \frac{3[\vec{p} \cdot \frac{\vec{r} - \vec{r}'}{|\vec{r} - \vec{r}'|}](\vec{r} - \vec{r}') - \vec{p}}{4\pi\epsilon_0 |\vec{r} - \vec{r}'|^3}$ . Finally, it is simplified to  $\frac{1}{4} \left\{ \frac{3[\vec{p} \cdot (\vec{r} - \vec{r}')](\vec{r} - \vec{r}')}{|\vec{r} - \vec{r}'|^5} - \frac{\vec{p}}{|\vec{r} - \vec{r}'|^3} \right\}$ .

So, combining all these I can write  $E$  as  $\vec{p} \cdot \vec{r} / r^3$  with the 3 here minus  $\vec{p}$  over  $4\pi\epsilon_0 r^3$ , this is the expression for a dipole sitting with any orientation now at the origin. Because, now I am taking the dot product, so it does not really matter dot product gives me that cosine theta already. If the dipole is at let us say  $r'$  some point  $r'$ , then this  $r$  would represent the distance from that point and I am going to have  $E$  at  $r$  is going to be  $3 \vec{p} \cdot \text{unit vector in the direction of } r - r' \text{ unit vector in that direction}$ .

Unit vector  $r - r'$  divided by  $4\pi\epsilon_0 r - r'$  cubed, which explicitly I can also write as  $3 \vec{p} \cdot \text{vector } r - r' \text{ multiplied by vector } r - r'$ . Since, I have multiplied by the vectors I will divide by  $r - r'$  raise to 5 minus  $\vec{p}$  over  $r - r'$  cubed of course, there is a 1 over  $4\pi\epsilon_0$  outside.

(Refer Slide Time: 14:01)

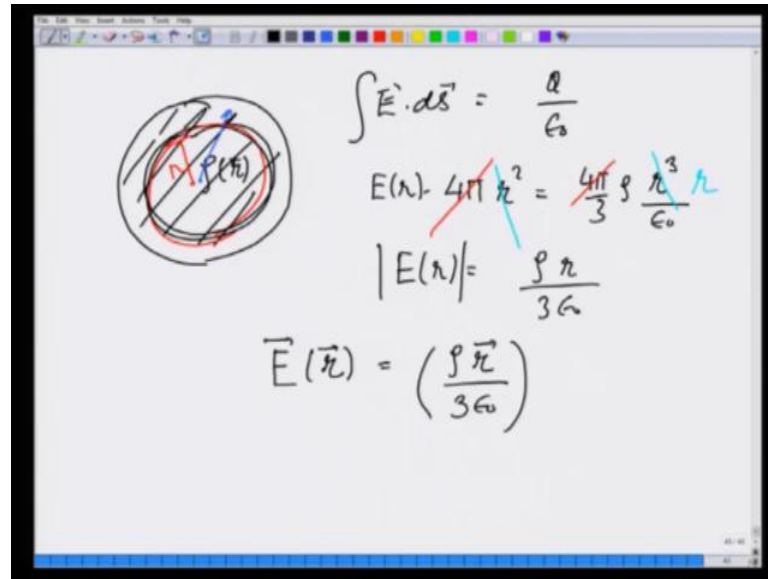

Next example I want to take we will use Gauss's law and in this I want to take a positively charge sphere superimpose it on a negatively charge sphere and calculate the field due to this super position of these two in this region, where they overlap. In a way you can think electrically this overlap region also to have no charge density, rho is 0. Because, positive and negative charges cancel, equivalently you can also think of this as being hollow, because electrically it does not matter.

So, in a way we are also calculating the electric field in a hollow region, this is hollow region when charge outside on one side is positive and charge on the other side is negative, these two centres are displaced by some distance  $a$ . I am finally, going to take the limit in this case, where these two charges with overlap for most of the regions. So, that this negative side will give me a very thin slice of negative charge, positive side will give me a very thin slice of positive charge.

And you can see in the middle the charges are going to have largest magnitude and it diminishes as you go to the side and this region is hollow by taking appropriate limits, limit  $a$  going to 0 and this charge density rho going to infinity. So, that the charge on the surface remains finite I will get the electric field due to a surface charge distribution rho theta or sigma theta which is some constant times cosine of theta and you will see that. So, again I am going to use a limiting process.

(Refer Slide Time: 16:49)

The image shows a handwritten derivation on a whiteboard. On the left, a sphere is drawn with a smaller concentric sphere inside it. A point  $P(r)$  is marked on the inner sphere. To the right, the following equations are written:

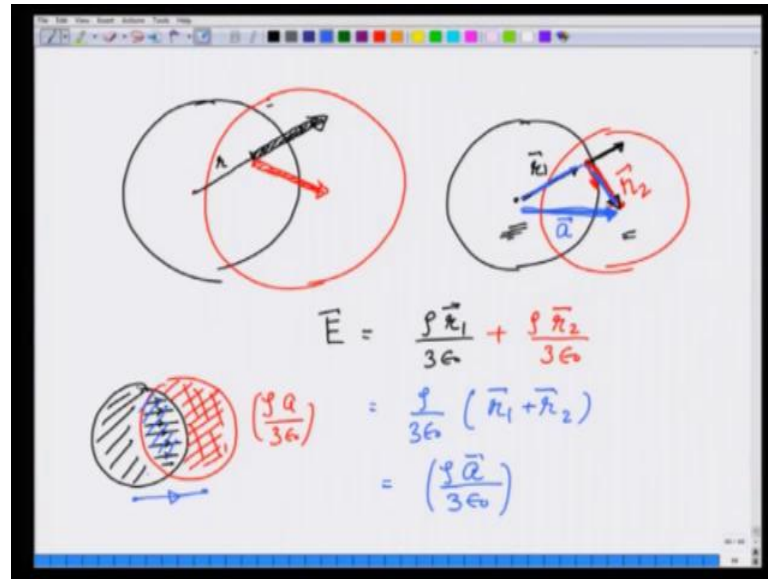

$$\int \vec{E} \cdot d\vec{s} = \frac{Q}{\epsilon_0}$$
$$E(r) \cdot 4\pi r^2 = \frac{4\pi}{3} \rho \frac{r^3}{\epsilon_0}$$
$$|E(r)| = \frac{\rho r}{3\epsilon_0}$$
$$\vec{E}(r) = \left( \frac{\rho r}{3\epsilon_0} \right)$$

So, let us take a sphere with uniform charge density  $\rho$  and this problem you have solved in your 12th grade, if you apply Gauss's law and calculate the field inside at a distance  $r$  this field comes out to be  $\rho r$  by  $3 \epsilon_0$ . But, let us do it explicitly anyway  $E \cdot d s$  gives me charge enclosed divided by  $\epsilon_0$ . So, if I take the inner surface  $E \cdot d s$  is going to be  $E$  at  $r$  times  $4 \pi r^2$  and charge enclosed is  $4 \pi$  by  $3$   $\rho r^3$  divided by  $\epsilon_0$  here  $4 \pi$  cancels, this  $r^2$  cancels and gives me a single  $r$ .

And therefore, field at  $r$  comes out to be  $\rho$  magnitude of field at  $r$  comes out to be  $\rho r$  over  $3 \epsilon_0$ , if I write the vector field  $\vec{E}$  at  $r$  its direction is radially out and using this spherical polar coordinates I can write this as  $\rho$  vector  $r$  divided by  $3 \epsilon_0$  this is the field.

(Refer Slide Time: 18:22)

Now, let us superimpose these two charges that we were talking about, here is the positive charge, here is the negative charge, positive charge at this distance  $r$  gives me a field which is going like this radially out. If I look at the negative charge it gives me a field like this towards the centre, because the negative charge at any point. So, let me make this picture again, let me take any point, let us say point out here, here is electric field due to positive charge and here is electric field due to negative charge.

If I call this vector  $r_1$  and call this vector from the point where I am calculating the electric field towards the centre  $r_2$ , then the electric field at this point is equal to some due to the field due to the positive charge plus that due to the negative charge. So, I am going to write this as  $\frac{\rho r_1}{3 \epsilon_0}$ . And since  $r_2$  is already in the direction where the in the direction of the electric field I can write this as plus  $\frac{\rho r_2}{3 \epsilon_0}$  combine them together I can take  $\rho$  over  $3 \epsilon_0$  out I have  $r_1$  plus  $r_2$ , this is  $r_1$  vector, this is  $r_2$  vector.

So, their sum is this vector whose magnitude that distance between the centres of these spheres and vector is from positive charge towards the negative charge. So, I can write this as  $\frac{\rho \vec{a}}{3 \epsilon_0}$ , this is very interesting result. Because, now you look at this contribution of the two fields, if I take this negative charge here and the positive charge here in this hollow region field is the same everywhere it is pointing from negative to positive side it is magnitude is  $\rho a$  divide by  $3 \epsilon_0$  provided these two densities are the same that is how everything worked out.

And its direction is from the centre of the positive charge towards the centre of the negative, this is a very interesting result no matter what you do field inside is constant in this hollow region. Now, we are going to use this fact to derive field due to a surface charge distribution.

(Refer Slide Time: 21:37)

Let me now take these spheres to be overlapping over most of the regions and they are displaced by small vector  $a$ , these are the centres. Let us now take how much is the charge in this region, now since I am going to use this spherical polar coordinates it will be useful if I make this arrangement in the vertical direction, this is the centre of the two spheres. Because, the distance between them is very small I can take almost a common centre and I want to calculate the charge in this volume.

Remember, how much is the volume element, this small volume element  $dV$  is going to be again  $a$  is very, very small  $a$  is much, much, much less than the radius of these spheres  $a$  in fact, will tend to 0. So, I can write this as  $R^2 d \cos \theta$ , because this angle is  $\theta$   $d\phi$  times  $dr$ , where  $dr$  is this distance along the radial direction. So, again I am taking this particular volume element, this distance is  $dr$  how much is  $dr$ ? Remember what we said, we said these are displaced by distance  $a$ .

So, this distance here is  $a$ , this distance here is  $a$  and this is  $dr$ , this angle is  $\theta$ . So, you can see that  $dr$  is  $a \cos \theta$ , so I can write this small volume element as  $R^2 d \cos \theta d\phi$  times  $a \cos \theta$ . And therefore, the charge in this

region  $dQ$  is going to be  $\rho a \cos\theta$ , let me bring a also here times  $R^2 \sin\theta d\theta d\phi$ , recall from our one of our previous lectures this is nothing but the area element in the radial direction for this sphere. So, this is nothing but a  $\rho a \cos\theta ds$ .

(Refer Slide Time: 24:46)

$(\rho a \cos\theta) ds = \sigma(\theta) ds$   
 $\sigma(\theta) = \rho a \cos\theta$   
 limit  $a \rightarrow 0$   $\rho \rightarrow \infty$   
 $\rho a \rightarrow \sigma_0$   
 $\sigma(\theta) = \sigma_0 \cos\theta$   
 $\vec{E} = \frac{\rho a}{3\epsilon_0} = \frac{\rho a (-\hat{z})}{3\epsilon_0}$   
 $= -\left(\frac{\sigma_0}{3\epsilon_0}\right) \hat{z}$

So, what I have the situation now if I think of this as single sphere, I have positive charge here which is  $\rho a \cos\theta ds$  which I can write as a surface charge density  $\sigma$  times  $ds$ , where  $\sigma$  depends on  $\theta$  and  $\sigma(\theta) = \rho a \cos\theta$ . In the limit of  $a$  going to 0 and  $\rho$  going to infinity, such that  $\rho a$  goes to some  $\sigma_0$  I can write  $\sigma(\theta)$  as  $\sigma_0 \cos\theta$ . But, these are two displaced spheres. So, what will the field look like, field will be in the direction of displacement from positive to negative side.

And therefore, the electric field which remember earlier we derived to be  $\rho a / 3\epsilon_0$  is going to be  $\rho a$  it is in the minus  $z$  direction divided by  $3\epsilon_0$ . But,  $\rho a$  we have said is nothing but  $\sigma_0$ . So, this is  $\sigma_0 / 3\epsilon_0$   $z$  in the minus  $z$  direction.

(Refer Slide Time: 26:14)

What do we conclude? We conclude that if I have a sphere over which sigma depends on the angle from some axis, some axis if you go away by an angle theta, if sigma theta is sigma 0 cosine of theta. So, that it is positive all over here and negative on the other side maximum being along this axis and then it diminishes and becomes 0 here. Then, E field is constant inside and as is given by sigma naught over 3 Epsilon 0 pointing from positive to negative side. That is a very important result, you also learnt in this how to use Gauss theorem with two charge distributions and it gives you a result that for a particular surface charge density you get a constant field inside this is sphere.
