Lecture - 68
Assignment 2
Problems 1-4

(Refer Slide Time: 00:15)

In this tutorial and next we will be solving home assignment number 2, which is on basic electrostatics and vector calculus. Problem number one of this assignment says for a given field F , which is a function of x and y is equal to $2x \hat{i} + 3y \hat{j}$. The dot product $F \cdot ds$, where ds represent an infinitesimal area on a cylinder of radius R . So, we wish to find the $F \cdot ds$ product. So, this is infinitesimal area on cylinder of radius R at an angle ϕ , and we are using cylindrical coordinates. So, if I make a picture of the cylinder we are trying to look, there is a force field F and we are trying to find the dot product of $F \cdot ds$, where this small area is at an angle ϕ at radius R .

So, you can see in cylindrical coordinate this area is actually going to point in the direction of \hat{s} - unit vector in cylindrical coordinates, its height is dz or Δz . This angle is $d\phi$, therefore this area magnitude. So, if I write ds magnitude is going to be $R d\phi dz$ which is this distance, let me show it by red the curve distance of the curved surface, and the height is dz . So, magnitude is going to be $R d\phi dz$, and the direction is \hat{s} in the x direction. So, ds area is $R d\phi dz$ in the \hat{s} direction. And therefore, when I

calculate $\vec{F} \cdot d\vec{s}$ is going to be $2x \hat{i} \cdot \hat{s} R d\phi dz$ plus $3y \hat{j} \cdot \hat{s} R d\phi dz$.

(Refer Slide Time: 03:21)

$$\begin{aligned}
 x &= R \cos \phi & \hat{i} \cdot \hat{s} &= \cos \phi \\
 y &= R \sin \phi & \hat{j} \cdot \hat{s} &= \sin \phi \\
 \vec{F} \cdot d\vec{s} &= (2R \cos^2 \phi + 3R \sin^2 \phi) R d\phi dz \\
 &= R^2 (2 \cos^2 \phi + 3 \sin^2 \phi) d\phi dz \\
 &= R^2 (2 + \sin^2 \phi) d\phi dz.
 \end{aligned}$$

②

$$\int_{\pi/4}^{3\pi/4} \int_0^1 R^2 (2 + \sin^2 \phi) dz d\phi$$

Now, I know in cylindrical coordinates on the surface x is going to be $R \cos$ of ϕ $\hat{i} \cdot \hat{s}$ unit vector is \cos of ϕ , y is $R \sin$ of ϕ $\hat{j} \cdot \hat{s}$ is \sin of ϕ . And therefore, $\vec{F} \cdot d\vec{s}$ is going to be equal $2R \cos^2 \phi + 3R \sin^2 \phi$ and then we have from outside $R d\phi dz$ which becomes equal to $R^2 (2 \cos^2 \phi + 3 \sin^2 \phi) d\phi dz$ which by using the identity that $\cos^2 \phi + \sin^2 \phi$ is 1, I can also write as $R^2 (2 + \sin^2 \phi) d\phi dz$, and that is the answer. For question number 2 - the answer, the question is the flux of the field in problem 1 over a quarter of a cylindrical surface extending from $\phi = \pi/4$ to $\phi = 3\pi/4$ and z from 0 to 1.

So, what we are now asking for, let me again make this cylinder and we are taking the length of the cylinder to be 1, over this length of 1, we want to integrate from $\phi = \pi/4$ up to $\phi = 3\pi/4$. So, in the somewhere like this over this cylindrical surface which is on the back side, we wish to calculate the flux passing through this cylindrical surface. So, what we need to do is integrate $\vec{F} \cdot d\vec{s}$ over the surface which is going to be equal to $\int_{\pi/4}^{3\pi/4} \int_0^1 R^2 (2 + \sin^2 \phi) dz d\phi$. So, it is from whatever length let us say 0 to 1, because there is no z dependence it does not

matter, what they initial and final points are $R^2 \int_{\pi/4}^{3\pi/4} (2 + \sin^2 \phi) d\phi$. Now, z integral since there is no z dependence gives me 1.

(Refer Slide Time: 06:06)

The image shows a whiteboard with the following handwritten derivation:

$$\begin{aligned} \Phi &= R^2 \int_{\pi/4}^{3\pi/4} (2 + \sin^2 \phi) d\phi \\ &= 2R^2 \times \left(\frac{3\pi}{4} - \frac{\pi}{4} \right) + R^2 \int_{\pi/4}^{3\pi/4} \frac{(1 - \cos 2\phi)}{2} d\phi \\ &= 2R^2 \times \frac{\pi}{2} + \frac{R^2}{2} \left[\frac{\pi}{2} - \frac{1}{2} \sin 2\phi \right]_{\pi/4}^{3\pi/4} \\ &= \frac{5\pi R^2}{4} + \frac{R^2}{2} \end{aligned}$$

And therefore, I get this flux is equal to integral $d\phi$ from $\pi/4$ to $3\pi/4$ R^2 square comes out $2 + \sin^2 \phi$ which is equal to $2R^2$ times $3\pi/4 - \pi/4$, that is the first term plus R^2 square integration $\frac{1 - \cos 2\phi}{2} d\phi$ from $\pi/4$ to $3\pi/4$, which is equal to $2R^2$, sorry this is R^2 square; R^2 square times $\pi/2$ plus R^2 square by 2 inside I am going to get $\pi/2$ to from the first term, minus $\frac{1}{2} \sin 2\phi$ from $\pi/4$ and $3\pi/4$. And this integral you can easily do and the final answer then comes out to be $\frac{5\pi R^2}{4} + \frac{R^2}{2}$. The integral that is quite simple to do, so I leave them for you.

(Refer Slide Time: 07:27)

③ $\rho(x, y, z) = \rho(r, \theta, \phi)$
 $= C z^2 |z|$

$dV = r^2 dr \sin\theta d\theta d\phi$
 $\rho(r, \theta, \phi) = C z^2 |z|$
 $= C (r^3 \sin^2\theta \cos^2\phi) |r \cos\theta|$

$dm = \rho \cdot dV$
 $= C r^3 \sin^2\theta \cos^2\phi |r \cos\theta|$
 $\cdot r^2 dr \sin\theta d\theta d\phi$
 $= C r^5 \sin^3\theta |r \cos\theta| \cos^2\phi dr d\theta d\phi$

Question number 3 is if the density of the matter distributed in a part of space is given as. So, let me write density which is a function of x, y and z; I could also write it as density R theta and phi is given as C x square modulus of z. What it means is in the lower plane or z negative value or positive value its positive. And x it depends on x square, so density all positive. It is given as C x square mod z, where C is a constant the mass of in infinite dissimilar volume element in spherical polar co ordinates is given as.

So, we want to fine mass of a small volume element. Let me again make a picture, you recall that the volume element in spherical polar coordinates is going to be between theta and d theta, and it is going to look like this, where stands the distance this is small d R, you moving along d theta and when you move in the x y axis, the angel is d phi. So, the volume element is given as d v is equals to r square d r sin theta d theta d phi, the density in terms of R theta and phi is given as C x square mod z, which I am going to change in spherical polar co ordinates. So, this still becomes C r square sin square theta cosine square phi and then z is nothing but r; r is again or only positive numbers. So, cosine theta would be positive and negative, so I will put it more mode cosine of theta.

And therefore, this small mass is going to be equal to rho times d v which is C r cubed this term here, and this term here become r cubed times sin square theta cos square phi mod cosine of theta, and then you have r squares d R sin theta d theta d phi d phi, which I

can then finally write as $C r^5 \sin^3 \theta \cos^2 \phi$ modulus of cosine of theta cosine square phi d R d theta d phi, that is the mass element.

(Refer Slide Time: 10:39)

④ $\rho(r, \theta, \phi) = C r^2 |z|$
 $= C r^3 \sin^2 \theta \cos^2 \phi |\cos \theta|$
 $dm = \int C r^5 \sin^3 \theta |\cos \theta| \cos^2 \phi dr d\theta d\phi$
 $M = C \int_0^R dr r^5 \int_0^\pi d\theta \sin^3 \theta |\cos \theta| \int_0^{2\pi} \cos^2 \phi d\phi$
 $\int_0^R dr r^5 = \frac{R^6}{6}$; $\int_0^{2\pi} \cos^2 \phi d\phi = \frac{1}{2} \int_0^{2\pi} (1 + \cos 2\phi) d\phi$
 $= \pi$

Question number 4, then ask mass of the sphere of radius r centered around the with density distribution $C x^2 |z|$ is. So, now, we are asking, if I have a sphere centered at the origin of radius r with this mass density $\rho = C r^2 |z|$ and ϕ is equal to $C x^2 |z|$ which we have already written as $C r^3 \sin^2 \theta \cos^2 \phi |\cos \theta|$. What is the total mass of a sphere of radius R centered at the origin. We have already calculated small mass element of its small volume element here, which is given as we have written in previous page, I am going to copy it from here. $C r^5 \sin^3 \theta \cos^2 \phi$ modulus of cosine of theta cosine square phi d R d theta d phi. And therefore, the total mass is going to be an integral of this, now let me write this integral separately. So, total mass m is going to be given as, C is a constant which comes out and integral $d r r^5$ goes from 0 to R integral $d \theta \sin^3 \theta \cos^2 \phi$ theta goes from 0 to π an integral 0 to 2π cosine square, phi that is the answer. Now I can do these 3 integral separately.

So, 0 to R $d r r^5$ gives me, $R^6/6$, similarly the integral over $\sin^3 \theta \cos^2 \phi$, I forgot to write $d \phi$ here $d \phi$ 0 to 2π is nothing but $1/2$ integral 0 to 2π $1 + \cos 2 \phi$ $d \phi$ which gives me nothing but π which gives me.

(Refer Slide Time: 13:14)

$$\begin{aligned}
 \int_0^{\pi} \sin^3 \theta |\cos \theta| d\theta &= \int_0^{\pi} \sin^2 \theta |\cos \theta| \sin \theta d\theta \\
 &= -\int_0^{\pi} \sin^2 \theta |\cos \theta| d(\cos \theta) \\
 x &= \cos \theta \\
 &= -\int_1^{-1} (1-x^2) |x| dx \\
 &= \int_{-1}^1 (1-x^2) |x| dx
 \end{aligned}$$

Final integral this d theta integral, let me do that in the next page which is 0 to pi sin cube theta modulus of cosine theta d theta, which I can write it as to make life easy 0 to pi sin square theta modulus cosine theta cos theta, sorry sin theta d theta which is nothing but integral 0 to 2 pi sin square theta modulus cosine of theta d of cosine of theta with the minus sign in outside. Let us now define x as cosine of theta, then I have this integral equal to minus 1 to 1 sin square theta will be become 1 minus x square modulus of x d x which is nothing but minus 1 to 1 1 minus x square mode x d x.

(Refer Slide Time: 14:24)

$$\begin{aligned}
 &\int_{-1}^1 (1-x^2) |x| dx \quad \left| \begin{array}{l} |x| = -x \quad -1 \leq x \leq 0 \\ = x \quad 0 \leq x \leq 1 \end{array} \right. \\
 &= -\int_{-1}^0 (1-x^2) x dx + \int_0^1 (1-x^2) x dx \\
 &= \frac{1}{2} \\
 &\rightarrow 2 \int_0^1 (1-x^2) x dx = 1 \\
 M &= C \times \frac{R^6}{6} \times \frac{1}{2} \times \pi = \frac{\pi C R^6}{12}
 \end{aligned}$$

Let us do this integral. So, I have $\int_{-1}^1 \sqrt{1-x^2} dx$; the $\sqrt{1-x^2}$ on the side mode x is equal to $-\sqrt{1-x^2}$ for x between -1 and 0 , and is equal to $\sqrt{1-x^2}$ for x between 0 and 1 . So, I can write this equal to this integral therefore, becomes equal to $\int_{-1}^0 -\sqrt{1-x^2} dx + \int_0^1 \sqrt{1-x^2} dx$. These are very easy integral to perform and the final answer they give you, when you do all the integral comes out to be $\frac{1}{2}\pi$. Another way of looking at it is since $\sqrt{1-x^2}$ is even about $x=0$, I could have written this as $2 \int_0^1 \sqrt{1-x^2} dx$ which will give me $\frac{1}{2}\pi$. So, the total mass, therefore if I collect all term is going to $C \times R^6 \times \frac{1}{2}\pi$, which comes out to be $\frac{1}{2}\pi C R^6$, and that is your answer.
