**Properties of plane surfaces – VI: Parallel axis transfer theorem for second moment and product of an area**

Having defined these quantities, the 2<sup>nd</sup> moment of inertia and product of inertia, we now describe a relationship between the 2<sup>nd</sup> moment of an area about its set of axis passing through the centroid of the body and another set XY axis which are parallel to those passing through the centroid.

(Refer Slide Time: 0:36)

Thus suppose I have an area, the centroid with respect to a given set of axis X and Y with origin at O such that the coordinates of its centroid are X<sub>0</sub> and Y<sub>0</sub>. 2 is another set of parallel axis X prime and Y prime passing through the centroid. X prime is parallel to X and Y prime is parallel to Y. And we want to now calculate, show that I<sub>xx</sub> I<sub>x'x'</sub> are related by a very simple theorem and so are the other moments.

Thus I<sub>xx</sub> is equal to  $\int y^2 dA$ . So suppose I have a small area DA here, this is Y which is also equal to Y is equal to Y prime where Y prime is the Y coordinate of the same area with respect to X prime and Y prime axis + Y<sub>0</sub><sup>2</sup> DA. And this is equal to Y prime square DA +

$Y_0^2 DA + 2Y_0 \int Y' DA$ . Notice that  $\int Y'^2 DA$  is the centroidal moment of inertia about the  $X'$  axis passing through the centroid.

And  $\int Y' DA$  is nothing but area times the  $Y$  coordinate in the centroid frame. So this is going to be 0. If I calculate the centroid with the origin at the centroid the coordinates of the centroid are going to come to 0 and therefore I see that  $I_{XX}$  is equal to  $\int Y'^2 DA$  that is  $I_{X'X'} + Y_0^2 \times \text{entire area}$ . This way if I know the 2<sup>nd</sup> moment of inertia of a body about an axis passing through its centroid, I can easily calculate the 2<sup>nd</sup> moment of inertia of the same body with respect to an axis which is parallel to the 1<sup>st</sup> axis but displaced by amount  $Y_0$ .

(Refer Slide Time: 3:38)

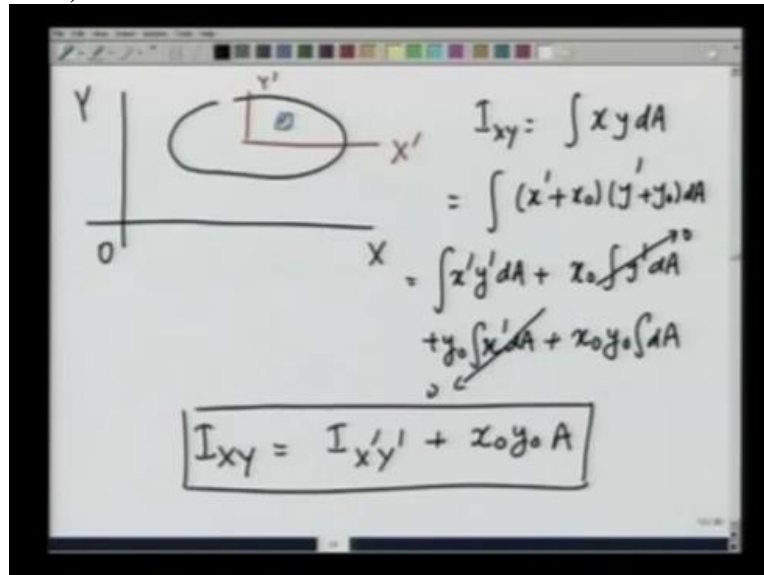

In the same manner we cannot calculate  $I_{YY}$  which is equal to  $\int X^2 DA$  which I can write as  $\int X'^2 DA + X_0^2 DA$ . Let me for convenience show in the picture again what we are talking about. This is the body. This is the centroid set of axis  $X'$ ,  $Y'$ . This is  $X$ ,  $Y$ ,  $O$ , this is  $X_0$ , this is  $Y_0$ . So if I choose an area here, this is  $X$  and this is  $X'$ .

$X$  is  $X' + X_0$ . So this can be written as equal to  $\int X'^2 DA + X_0^2 \int DA + 2X_0 \int X' DA$ . This again by the same logic as we applied earlier that this is the  $X$  coordinate of the centroid in the coordinate system which has its origin at the centroid itself. So this is 0. So I get  $I_{YY}$  is equal to  $I_{Y'Y'} + X_0^2 A$ .

So it is as if the entire area is concentrated at the centroid + whatever the 2<sup>nd</sup> moment of area is about the axis passing through the centroid.

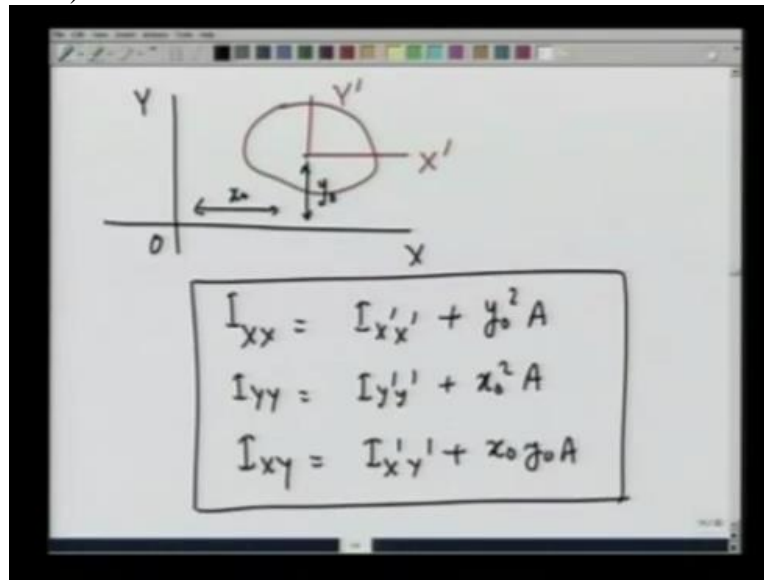

(Refer Slide Time: 5:25)

Next, let us calculate the product of area again making these axis X prime, Y prime. X, Y, O and I take an area here. The product is IXY which is equal to integral XYDA and I substitute for X and Y as X prime + X0 Y prime + Y0 DA which comes out to be X prime Y prime DA + X0 integral Y prime DA + Y0 integral X prime DA + X0Y0DA. Again by the arguments that we have used earlier, these 2 terms drop to 0.

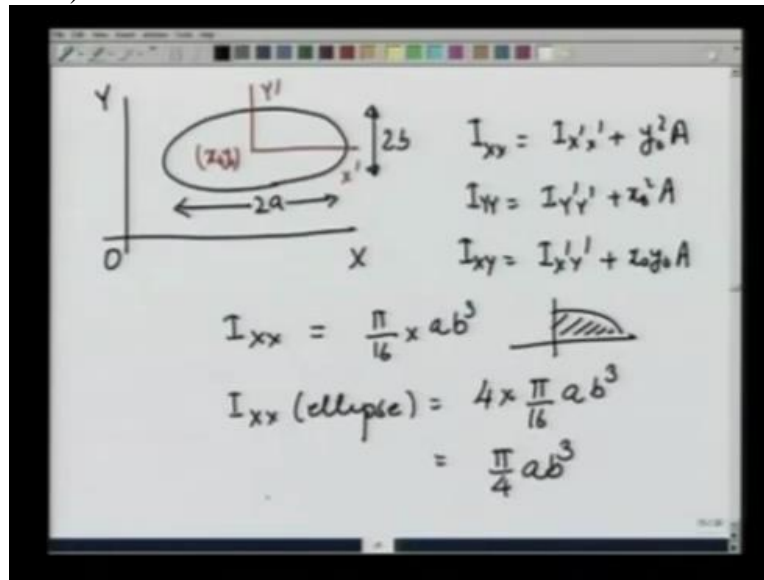

And therefore IXY is equal to IX prime Y prime + X not Y0 times A for area. So what we have learned this if we know the 2<sup>nd</sup> moment of inertia and the product of inertia about a set of axis passing through the centroid, I can calculate about any other set of axis which are parallel to those passing through the centroid. Let us summarise these.

(Refer Slide Time: 6:58)

So for an area whose 2<sup>nd</sup> moment and product of area are known about the axis passing through the centroid, I have in general  $I_{xx}$  equals  $I_{x'x'} + y_0^2 A$  where  $y_0$  is the coordinate of the centroid.  $I_{yy}$  is equal to  $I_{y'y'} + x_0^2 A$  and  $I_{xy}$  equals  $I_{x'y'} + x_0 y_0 A$ . These are known as transfer theorem. Using these, I can transfer the moment of area or the product of area from one coordinate system to another.

(Refer Slide Time: 8:07)

As an example of the application of transfer theorem, let us take case of an ellipse with its length being  $2A$  and this being  $2B$ , with its centroid at point  $X_0, Y_0$  and calculate its moment of area, 2<sup>nd</sup> moment of area and product of area with respect to the  $XY$  axis shown here. So by transfer theorems I have  $I_{XX}$  equals  $I_{X'X'}$  +  $Y_0^2$  times the area of the ellipse.  $I_{YY}$  similarly is  $I_{Y'Y'}$  +  $X_0^2$  times the area of the ellipse.

And  $I_{XY}$  is equal to  $I_{X'Y'}$  +  $X_0 Y_0$  times the area of the ellipse where  $I_{X'X'}$   $X'$  is the 2<sup>nd</sup> moment of area with respect to the  $X'$  axis parallel to the  $x$ -axis passing through the centroid.  $I_{Y'Y'}$  is the 2<sup>nd</sup> moment of area with respect to the  $Y'$  axis parallel to the  $Y$  axis and passing through the centroid. Previously we have calculated  $I_{XX}$  as  $\frac{\pi}{16}$  times  $AB^3$  for a quarter of an ellipse like this.

So for the full ellipse and this I left as an exercise for you there, this is going to be 4 times as much. So this is going to be  $\frac{\pi}{16}$   $AB^3$  which this  $\frac{\pi}{4}$  for  $AB^3$ .

(Refer Slide Time: 10:17)

$$I_{y'y'} (\text{ellipse}) = 4 \times \frac{\pi}{16} a^3 b$$
$$= \frac{\pi}{4} a^3 b$$
$$I_{x'y'} = 0$$
$$\left( \begin{array}{l} I_{xx} = \frac{\pi}{4} ab^3 + y_0^2 \pi ab \\ I_{yy} = \frac{\pi}{4} a^3 b + x_0^2 \pi ab \\ I_{xy} = 0 + x_0 y_0 \pi ab \end{array} \right)$$

Similarly  $I_{y'y'}$  for the ellipse is going to be 4 times pi over 16  $A$  cubed  $B$  which is pi over 4  $A$  cubed  $B$ . And  $I_{x'y'}$  is 0. Therefore, for this ellipse, we will have  $I_{xx}$  as pi by 4  $AB$  cubed which is the 2<sup>nd</sup> moment of area about the  $X$  prime axis passing through the centroid +  $Y_0$  square times pi  $AB$  because pi  $AB$  is the area of the ellipse.  $I_{yy}$  is going to be pi over 4  $A$  cubed  $B$  +  $X_0$  square pi  $AB$ .

And  $I_{xy}$  is going to be 0 which is the  $I_{x'y'}$ . By symmetry, it is 0 for axis passing through the centroid +  $X_0 Y_0$  pi  $AB$ . So using transfer theorems, we could calculate the 2<sup>nd</sup> moment of area and the product of area when it was given about the centroid.
