**Vector products and their geometric interpretation**

In the last lecture we had been looking at vectors. In particular how to represent them algebraically.

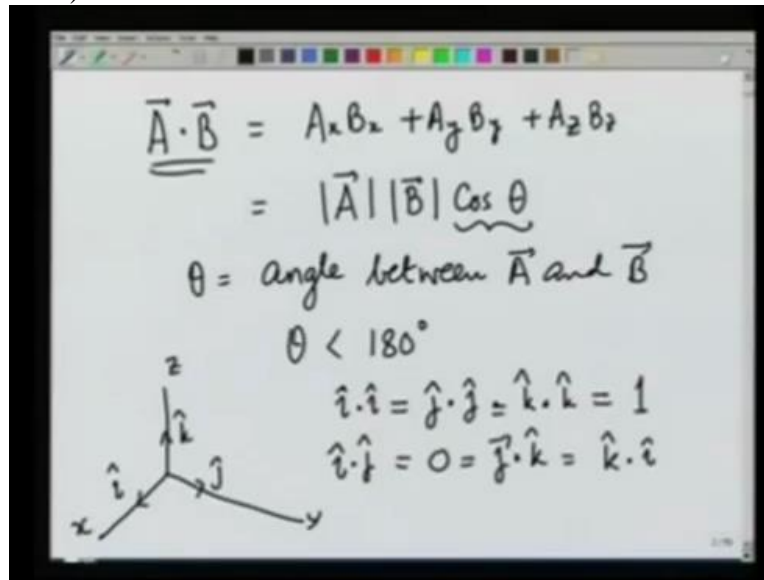

(Refer Slide Time: 0:23)

The image shows a whiteboard with handwritten mathematical formulas. The top formula is the scalar product:  $\vec{A} \cdot \vec{B} = A_x B_x + A_y B_y + A_z B_z$ . Below it, the text "Scalar Product" is written. The bottom formula is the vector product:  $\vec{A} \times \vec{B} = \begin{vmatrix} \hat{i} & \hat{j} & \hat{k} \\ A_x & A_y & A_z \\ B_x & B_y & B_z \end{vmatrix}$ . Below it, the text "Vector Product" is written.

And then we looked at the product of vectors and defined the scalar product which we wrote as  $A_x B_x + A_y B_y + A_z B_z$ . And a vector product which gives me a vector  $\vec{A} \times \vec{B}$ . And in a short way I wrote this as determinants of  $A_x, A_y, A_z, B_x, B_y$  and  $B_z$ . I had had asked you to check that this gives the correct answer. We define these 2 products in this manner because this satisfies certain transformation properties of vector components under rotation. Let us look at these products are slightly more carefully.

(Refer Slide Time: 1:40)

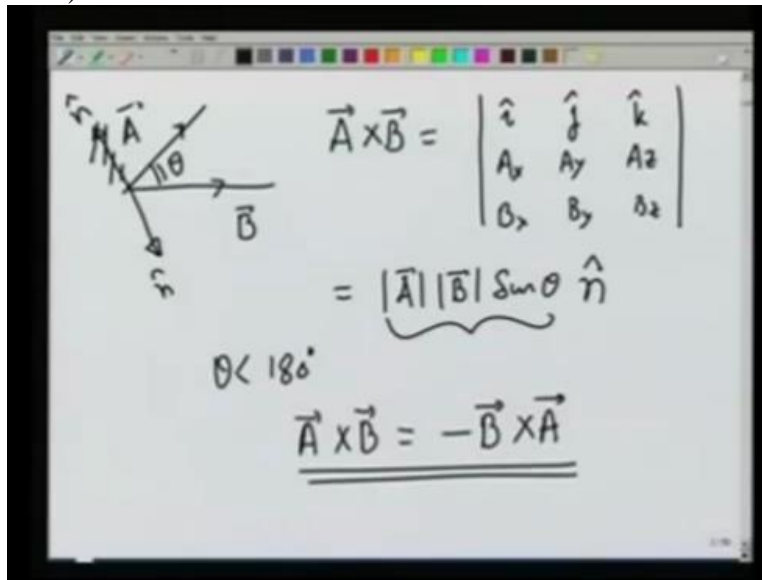

The image shows a whiteboard with handwritten mathematical notes. At the top, the dot product of two vectors  $\vec{A}$  and  $\vec{B}$  is given as  $\vec{A} \cdot \vec{B} = A_x B_x + A_y B_y + A_z B_z$ . This is then equated to the magnitude of  $\vec{A}$  times the magnitude of  $\vec{B}$  times the cosine of the angle  $\theta$  between them:  $\vec{A} \cdot \vec{B} = |\vec{A}| |\vec{B}| \cos \theta$ . Below this, it is noted that  $\theta$  is the angle between  $\vec{A}$  and  $\vec{B}$ , and that  $\theta < 180^\circ$ . To the left, a 3D Cartesian coordinate system is drawn with axes labeled  $x$ ,  $y$ , and  $z$ . Unit vectors  $\hat{i}$ ,  $\hat{j}$ , and  $\hat{k}$  are shown along the  $x$ ,  $y$ , and  $z$  axes respectively. To the right of the diagram, the dot products of these unit vectors are listed:  $\hat{i} \cdot \hat{i} = \hat{j} \cdot \hat{j} = \hat{k} \cdot \hat{k} = 1$  and  $\hat{i} \cdot \hat{j} = 0 = \hat{j} \cdot \hat{k} = \hat{k} \cdot \hat{i}$ .

So let us look at the dot product  $\vec{A} \cdot \vec{B}$  which is  $A_x B_x + A_y B_y + A_z B_z$ . This can also be written as magnitude of  $\vec{A}$  times magnitude of  $\vec{B}$  times cosine of  $\theta$  where  $\theta$  is the angle between  $\vec{A}$  and  $\vec{B}$ . And  $\theta$  is the smaller of the angle. So  $\theta$  is less than 180 degrees. In particular, if I look at the unit vectors along  $X$  direction,  $Y$  direction and  $Z$  direction, we find that  $\hat{i} \cdot \hat{i}$  is same as  $\hat{j} \cdot \hat{j}$ .

They are called equal to 1 because their magnitude is 1 and the angle between  $\hat{j}$  and  $\hat{j}$  or  $\hat{k}$  and  $\hat{k}$  is 0. Similarly  $\hat{i} \cdot \hat{j}$  is 0. So is  $\hat{j} \cdot \hat{k}$ . And so is  $\hat{k} \cdot \hat{i}$ . Notice that the dot product or the scalar product can be both negative and positive because cosine  $\theta$  can be negative or positive.

(Refer Slide Time: 3:37)

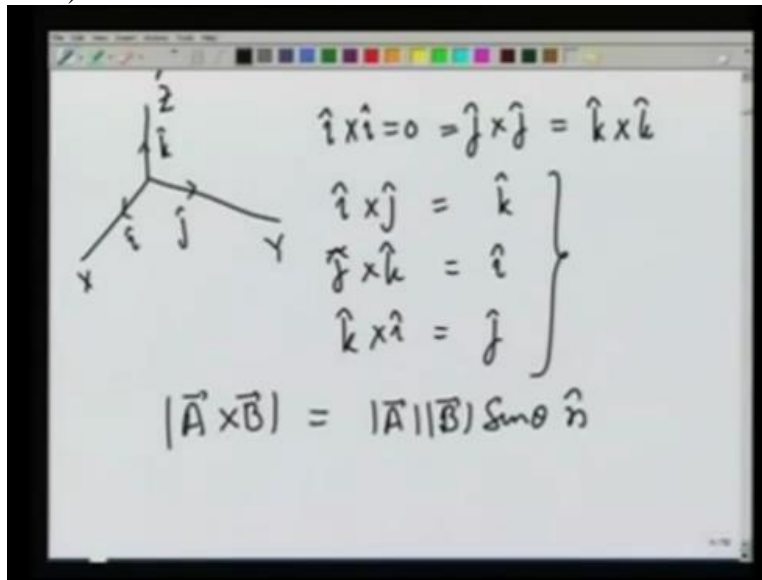

Similarly, if I look at 2 vectors A and B, then A cross B which I can write as the determinant I, J, K, AX, AY, AZ, BX, BY, BZ is also equal to magnitude of A times magnitude of B times sine of theta where theta is the smaller of the angle between A and B. So theta is less than 180 degrees, times a unit vector in the direction N where N is perpendicular to both A and B. So it is perpendicular to the plane formed by A and B.

So it will be somewhere like this. Maybe coming out of this plane of the board. How about whether N is this way or this way? This is answered by the right-hand rule. You turn A towards B through the smaller of the angle and the thumb gives you the direction of the vector product. So in this case, N would be going down.

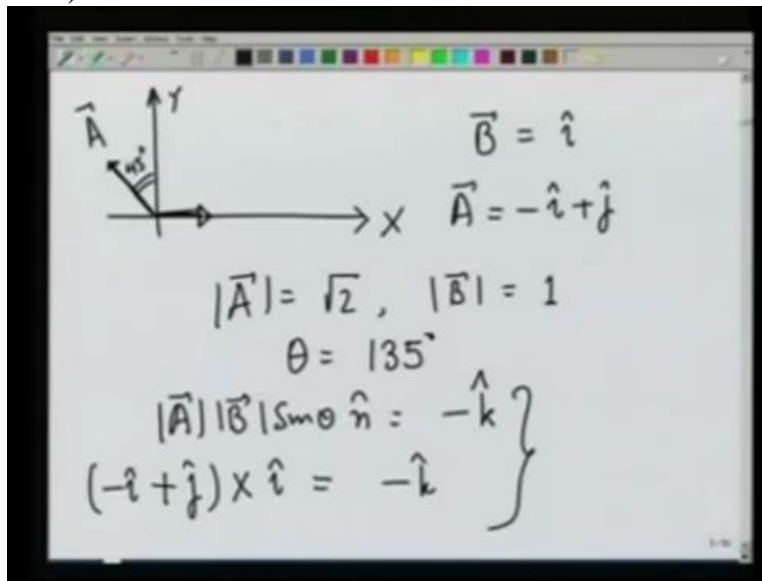

You can see that A cross B is going to be equal to - B Cross M because the magnitude will remain the same but the direction of N would change because now you will be turning B towards A. This is also clear from the components if you look at them carefully. So this is how the cross product works.

(Refer Slide Time: 5:29)

In particular if I look at the unit vectors, I, J, and K in X, Y and Z direction. Then I cross I is 0. And so is J cross J because the angle between them is 0. And so is K cross K. On the other hand, I cross J is equal to K. J cross K is equal to I and K cross I is equal to J. These are the relationships between the unit vectors. Let us now look at 1 or 2 examples where you see these relationships carefully. 1<sup>st</sup>, I want to show you that A cross B through an example is really equal to A B sine theta times N where N as I told you is in the sense of rotating A towards B through the smaller of the angles.

(Refer Slide Time: 6:40)

So let us for simplicity take this as X axis, this as Y axis. Consider B to be a vector, unit vector in X direction. So B is equal to I. And consider A vector to be in this direction which is 45 degrees from the Y axis or the X axis. So A is equal to -I + J. You can see that the magnitude of A base square root of 2, magnitude of B is one.

And the angle theta between them is 135 degrees. Therefore AB sine theta N is going to be equal to sine of 135 over root 2 is going to be equal to 1 times N. Turn A towards B through the smaller angle and that gives you a direction which is opposite to z-axis. So this is going to be -K. Let us see if you get the same answer if I explicitly do component wise vector product.

In that case, A cross B would be -I + J cross I. I cross I is 0 and J cross I is -K. So you see both give you the same answer. Now I want to demonstrate to you that A cross B gives you a vector that is perpendicular to both A and B.

(Refer Slide Time: 8:34)

The image shows a whiteboard with the following handwritten text:

$$\vec{A} \times \vec{B} = |\vec{A}| |\vec{B}| \sin \theta \hat{n}$$

$$\vec{A} \cdot (\vec{A} \times \vec{B}) = |\vec{A}| |\vec{A} \times \vec{B}| \cos \theta' = 0$$

$$\vec{B} \cdot (\vec{A} \times \vec{B}) = |\vec{B}| |\vec{A} \times \vec{B}| \cos \theta'' = 0$$

$$\vec{A} = 2\hat{i} + 3\hat{j} + \hat{k}$$

$$\vec{B} = -3\hat{i} + 4\hat{j} - 5\hat{k}$$

Below these equations, the dot products are listed:

$$\vec{A} \cdot (\vec{A} \times \vec{B}) \quad \vec{B} \cdot (\vec{A} \times \vec{B})$$

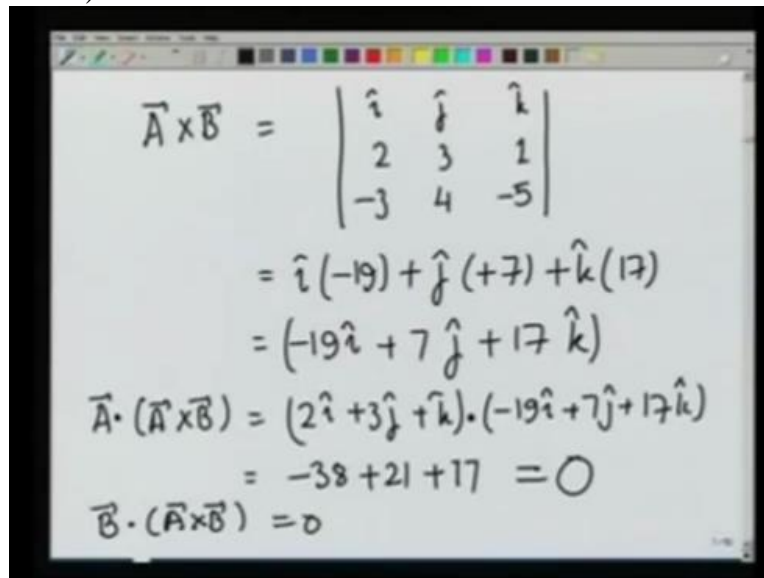

Since A cross B is equal to modulus A modulus B sine theta N where N is perpendicular to both A and B. That means that A dot A cross B which is equal to modulus of A cross B cosine of theta, let us call it theta prime because now this is the angle between A and A cross B should be 0. Because A cross B is in a direction perpendicular to A. And so, it should be B dot A cross B which is equal to modulus or magnitude of B magnitude of A cross B cosine of theta double prime.

Again, since A cross B is supposed to be perpendicular to A and B both, they should also be 0. Let us take an example. Let us take A to be a vector. Let us say 2I + 3J + K and B be a vector let

us say  $-3\mathbf{i} + 4\mathbf{j} - 5\mathbf{k}$ . We want to take their cross product or vector product and show that the resulting vector is really perpendicular to both A and B. So what we will do?

We will calculate A cross B and then take dot product with A and take dot product with B. So let us do that.

(Refer Slide Time: 10:26)

$$\begin{aligned}\vec{A} \times \vec{B} &= \begin{vmatrix} \hat{i} & \hat{j} & \hat{k} \\ 2 & 3 & 1 \\ -3 & 4 & -5 \end{vmatrix} \\ &= \hat{i}(-19) + \hat{j}(+7) + \hat{k}(17) \\ &= (-19\hat{i} + 7\hat{j} + 17\hat{k}) \\ \vec{A} \cdot (\vec{A} \times \vec{B}) &= (2\hat{i} + 3\hat{j} + \hat{k}) \cdot (-19\hat{i} + 7\hat{j} + 17\hat{k}) \\ &= -38 + 21 + 17 = 0 \\ \vec{B} \cdot (\vec{A} \times \vec{B}) &= 0\end{aligned}$$

So A cross B is going to be equal to I, J, K. Let us see what the vectors were? 2, 3, 1. So 2, 3, 1. And -3, 4 and -5. -3, 4 and -5. So the cross product is  $\mathbf{i} - 19 - 4$  so  $-19 + \mathbf{j} - 3 + 10$  so  $+7 + \mathbf{k} 8 + 9, 17$ . So this gives me a vector  $-19\mathbf{i} + 7\mathbf{j} + 17\mathbf{k}$ . This is A cross B. Let us take A dot A cross B which is equal to  $2\mathbf{i} + 3\mathbf{j} + \mathbf{k}$  dotted with  $-19\mathbf{i} + 7\mathbf{j} + 17\mathbf{k}$ .

Now I can use the distributive property and shown that I dot I is 1. So this is going to be  $-38$ , I dot J is 0, I dot K is 0. So no contribution from here.  $+3$  would multiply only with the J component  $+21$ . And K would be  $+17$  which is equal to 0. Since a and A cross B both magnitudes are nonzero, this can only happen if the angle between A and A cross B is 90 degrees.

I leave for you to show that B dot A cross B is also 0. Thus we see that A cross B is perpendicular to vectors A and B both.

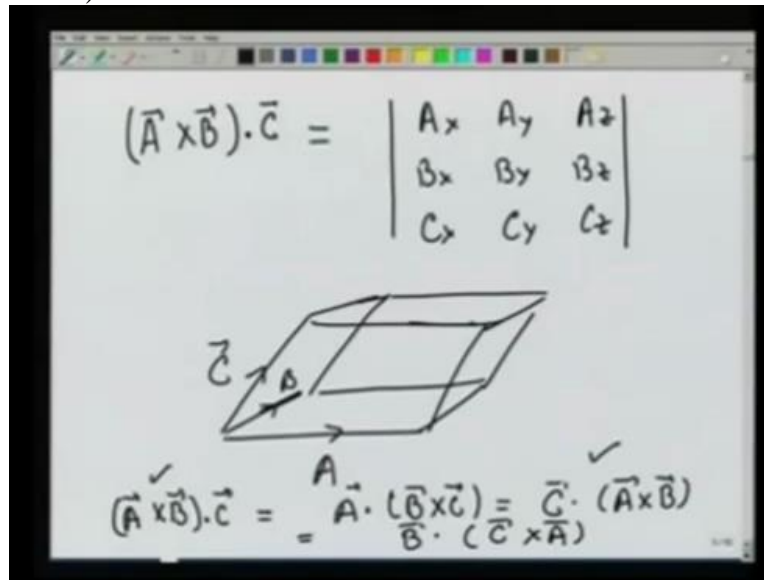

(Refer Slide Time: 12:44)

Let us now look at geometric interpretation of a cross product of a vector product. A cross product magnitude is nothing but magnitude of A magnitude of B times sine of theta where theta is the angle between them. So if there is a vector K and there is a vector B, angle between them is theta, you can see that A cross B is nothing but A times B sine theta. This is B magnitude.

So this is B sine theta. So this is the base times the height of this parallelogram. And therefore magnitude of A cross B is the area of parallelogram formed by A and B.

(Refer Slide Time: 14:22)

$$(\vec{A} \times \vec{B}) \cdot \vec{C} = \begin{vmatrix} A_x & A_y & A_z \\ B_x & B_y & B_z \\ C_x & C_y & C_z \end{vmatrix}$$

$$(\vec{A} \times \vec{B}) \cdot \vec{C} = \vec{A} \cdot (\vec{B} \times \vec{C}) = \vec{C} \cdot (\vec{A} \times \vec{B})$$

Next, we look at  $\vec{A} \times \vec{B}$  dotted with  $\vec{C}$ . This I leave for you to show that is  $A_x, A_y, A_z, B_x, B_y, B_z$  and  $C_x, C_y$  and  $C_z$  determinant, its value is equal to this. And this has a geometric interpretation of if I form a parallelepiped by vectors  $\vec{A}, \vec{B}$  and  $\vec{C}$ . It is the volume of this parallelepiped. So that is the geometric interpretation.

Since I can write  $\vec{A} \times \vec{B}$  dot  $\vec{C}$  as this determinant form, this also shows since determinant does not change if I change its rows twice, this is also equal to  $\vec{A}$  dot  $\vec{B} \times \vec{C}$ . This is also equal to  $\vec{C}$  dot  $\vec{A} \times \vec{B}$  which is same as this. And this one more term, this is also equal to  $\vec{B}$  dot  $\vec{C} \times \vec{A}$ . All these are equal. This is cyclically, the dot product and the cross product go like this. So this is a general review of vectors we obtain.
