**Wilson-Sommerfeld quantum condition II - Particle moving in a Coulomb potential in a plane and related quantum numbers**

(Refer Slide Time: 00:18)

So, the previous lecture I introduced the Wilson Sommerfeld quantum condition that said that for a periodic motion  $\oint p dx$  was equal to  $n h$  or the actions is quantized. So, let me write this inwards action is quantized in units of Planck's constant  $h$  and e applied this to applied this 2 number; one the simple harmonic oscillator that is the particle of mass  $m$  performing simple harmonic motion and we found that the energy  $n$  th level is given as  $n h \nu$  which matched with whatever explain the black body spectrum earlier and we also applied a 2; a particle moving in one dimension say along the  $x$  axis confined between  $x$  equals 0 and  $x$  equals  $L$  and we found that  $E_n$  was given as  $n^2 h^2$  over  $8mL^2$  square.

(Refer Slide Time: 02:27)

So,  $E_n$  was proportional to  $n^2$ ; let us now apply it to a 2 dimensional system which will correspond to Bohr model. So, recall what the Bohr model did Bohr model did was that it considered electrons to move by moving in circular orbits around the nucleus and because angular momentum is conserved the plane of the orbit is the same. We are going to now generalize this. So, we are going to generalize Bohr model to consider possibilities of other kinds of orbits and what are the other kinds of orbits from classical mechanics I know that in a  $1/r$  potential the orbits are elliptical in general; that means, what I can have is I can have an electron moving in a circle I can also have an electron moving in an elliptical orbit and how are these described and you will see that they come out naturally from Bohr Sommerfeld quantization condition.

(Refer Slide Time: 04:41)

Generalized momentum corresponding to a variable  $(x, y, z, \theta, \varphi \dots)$

(i) Write Energy  $E$  in terms of space variable (convenient)

(ii)  $p_X = \frac{\partial E}{\partial \dot{X}}$

$E = \frac{1}{2} m \dot{r}^2 + \frac{1}{2} m r^2 \dot{\varphi}^2 + V(r)$   
(planar polar coordinates)

$p_r = \frac{\partial E}{\partial \dot{r}} = m \dot{r}$      $p_\varphi = \frac{\partial E}{\partial \dot{\varphi}} = m r^2 \dot{\varphi}$

The diagram shows a 2D Cartesian coordinate system with x and y axes. A circle is drawn in the first quadrant, with a radius vector  $r$  from the origin to the circle's edge. The angle between the x-axis and the radius vector is labeled  $\varphi$ . The z-axis is shown as a vertical arrow pointing upwards from the origin.

So, in this again, now I am going to now first generalize the concept of momentum. Now I am going to call this generalized momentum and for our purposes for our purposes what I am going to do is define it in the following manner corresponding to a variable that variable could be  $x, y, z$  theta phi. So, I can take any variable to describe the position and define a generalize momentum. So, what we do for this is right step number one write energy  $E$  in terms of space variables whichever ask convenient and 2 p corresponding that variable let me for the time being; call it capital  $X$  is given as partial derivative of  $e$  divided by partial  $x$  dot.

So, let me give you an example, suppose a particle is moving in a 2 dimensional world then the energy,  $E$  is given as  $\frac{1}{2} m \dot{r}^2$  where  $r$  is the distance, plus  $\frac{1}{2} m r^2 \dot{\varphi}^2$  where  $\varphi$  is the angle from the  $x$  axis. So, what I am writing in the planner polar coordinates and in addition the potential energy which may depend on  $r$  in general a vector, but right now let it be  $r$ .

Then  $p_r$  will be defined as partial of  $E$  over partial  $r$  dot which will come out to be  $m \dot{r}$  similarly  $p_\varphi$  will be defined as partial  $e$  by partial  $\varphi$  dot which will come out to be  $m r^2 \dot{\varphi}$ . So, this is the concept of generalized momentum and let me show you why it is called generalized momentum.

(Refer Slide Time: 07:06)

$$E = \frac{1}{2} m \dot{r}^2 + \frac{1}{2} m r^2 \dot{\phi}^2 + V(r)$$

$$p_r = \frac{\partial E}{\partial \dot{r}} = m \dot{r} = \text{Dimensions of momentum (linear)}$$

$$p_\phi = \frac{\partial E}{\partial \dot{\phi}} = m r^2 \dot{\phi} = \text{Dimensions of Angular momentum}$$

Generalized momentum is NOT necessarily the same as linear momentum

Quantum Condition:

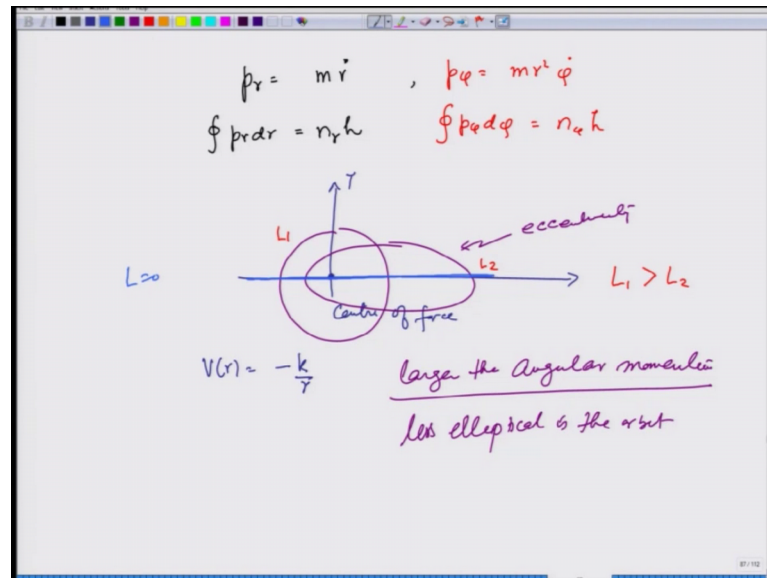

$$\oint p_r dr = n_r h \quad n_r = 0, 1, \dots$$

$$\oint p_\phi d\phi = n_\phi h \quad n_\phi = 0, 1, \dots$$

So, we considered a particle moving in 2 dimensional space; let us just confined our say as to 2 dimension x and y and we considered the variables that describes phi and r. So, we have energy which is one half m r dot square plus 1 half m r square phi dot square plus V r which may depend on the vector itself, but I will take v r only. So, that its central potential then p r which is d E by d r dot is m r dot and has dimensions of momentum that is linear momentum and p phi corresponding to variable phi is partial e over partial phi dot which is m r square phi dot and this has dimensions of angular momentum.

So, notice that generalized momentum is not necessarily same as linear momentum it could be angular momentum and the quantum condition now would be. So, the quantum condition in terms of generalized momentum would be integral p r; d r is equal to an interior n let me call it n r h an integral p phi d phi is going to be equal to sum n phi h where n r would be 0 1 and so on and phi could be 0 1 and so on; this is the quantum conditions now notice that now there are 2 conditions 2 quantum conditions one on r and 1 on phi and these 2 quantum conditions determine the orbit right. So, let us just spend some more time on this.

(Refer Slide Time: 09:52)

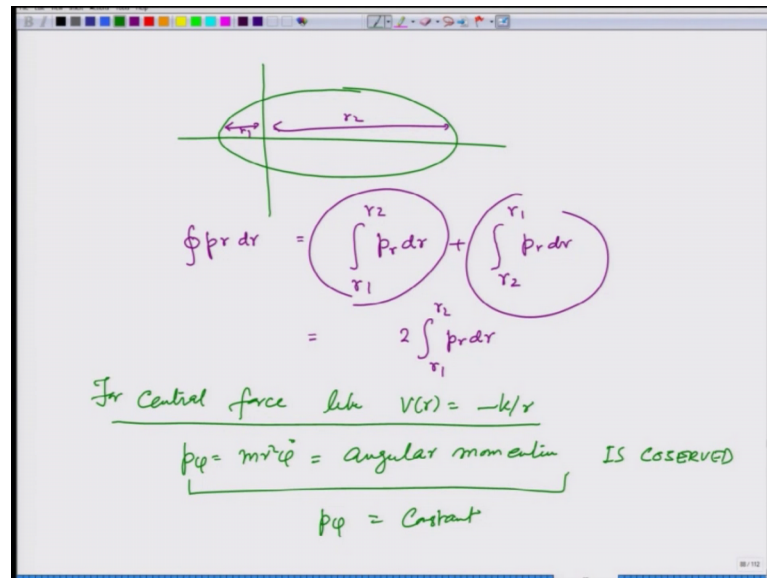

So, I have  $p_r$  which is  $m \dot{r}$  and  $p_\phi$  which is  $m r^2 \dot{\phi}$  and the corresponding quantum conditions  $\oint p_r dr$  and is equal to  $n_r h$  and  $\oint p_\phi d\phi$  and against this period is equal to  $m \dot{\phi} h$  input a could be.

What is happening is that if you consider the motion in the  $x y$  plane with centre of force, we know from classical mechanics that in this case if  $V(r)$  is equal to  $-\frac{k}{r}$  that is it is an attractive coulomb or gravitation kind of potential, then the orbits are like this either they could be circular or they could be elliptical and this has some eccentricity and larger the angular momentum less elliptical is the orbit. So, if I have considered suppose the circular orbit has a angular momentum  $L_1$  and the elliptical one is  $L_2$  and  $L_1$  could be greater than  $L_2$  this makes sense because if the angular momentum is 0 suppose angular momentum is 0  $L = 0$ , then the motion will be linear passing through the origin. So, in that case the motion will be linear passing through the origin.

So, smaller the angular momentum larger the ellipticity or extensity of the orbit right now let us supply quantum condition, now in this case is notice that for a given orbit.

(Refer Slide Time: 12:00)

So, if there is a given orbit like this, there is a distance  $r_1$  smaller distance  $r_2$  and when I calculate for example,  $p_r dr$ , I will be going from  $r_1$  to  $r_2$   $p_r dr$  plus to complete the full period I will be coming from  $r_2$  to  $r_1$   $p_r dr$  and that would give me both integrals give me the same answer because the symmetry and therefore, this is nothing, but 2 times  $r_1$  to  $r_2$   $p_r dr$ .

On the other hand for central force like  $V(r) = -k/r$ ,  $p_\phi$  which is  $m r^2 \dot{\phi}$  which is nothing, but the angular momentum is conserved this quantity is conserved and therefore,  $p_\phi$  is going to be constant for a central force. So, now, we are now ready to apply all this that we have done so far to calculate energy levels of the system doing a motion in a plane or in a planar orbit in coulombic force and that should give us the same answer as Bohr model.

(Refer Slide Time: 13:49)

$$V(r) = -\frac{k}{r}$$

$$= -\frac{1}{4\pi\epsilon_0} \frac{Ze^2}{r}$$

$$k = \left(\frac{Ze^2}{4\pi\epsilon_0}\right)$$

$$E = \frac{1}{2} m \dot{r}^2 + \frac{1}{2} m r^2 \dot{\phi}^2 - \frac{k}{r}$$

$$p_r = \frac{\partial E}{\partial \dot{r}} = m \dot{r} \quad 2 \int_{r_1}^{r_2} p_r dr = n_r h$$

$$p_\phi = \frac{\partial E}{\partial \dot{\phi}} = m r^2 \dot{\phi} = L$$

$$\oint m r^2 \dot{\phi} d\phi = L \int_0^{2\pi} d\phi = n_\phi h$$

$$L = \frac{n_\phi h}{2\pi} = n_\phi \hbar \rightarrow \text{Bohr's Condition}$$

What we are now doing is taking the motion of a particle in a plane around a potential centre which is minus  $k$  over  $r$  and the case of atoms it is nothing, but minus  $1$  over  $4\pi$  epsilon  $0$ ,  $z e$  square over  $r$  where  $e$  is the charge of the electron going around, alright, but for the time being just for convenience I will keep this as  $k$ . So,  $k$  equals  $z e$  square over  $4\pi$  epsilon  $0$  and the energy of the system is given as  $\frac{1}{2} m \dot{r}^2$  plus  $\frac{1}{2} m r^2 \dot{\phi}^2$  minus  $k$  over  $r$ ,  $p_r$  is equal to partial  $e$  over partial  $\dot{r}$  dot which is  $m \dot{r}$  and the corresponding quantum condition is  $\int_{r_1}^{r_2} p_r dr = n_r h$  the corresponding  $p_\phi$  equation is equal to partial  $e$  over partial  $\dot{\phi}$  dot which is  $m r^2 \dot{\phi}$ .

$\dot{\phi}$  which is a constant let us call this  $L$  and the corresponding condition is  $m r^2 \dot{\phi} d\phi$  over the whole period; that means, if I start from one point from this cross and go all over that is  $\int_0^{2\pi} d\phi$  this is equal to  $L \int_0^{2\pi} d\phi$ .

(Refer Slide Time: 15:58)

If we considered only circular orbits

$$p_r = m\dot{r} = 0, \quad L = n\phi h$$

$$E = \left( \frac{n\phi^2 \hbar^2}{2mR^2} - \frac{k}{R} \right)$$

with  $\frac{mv^2}{r} = \frac{k}{r^2} \Big|_{r=R}$

$\int p_r dr = \int m\dot{r} dr = n_r h$

$$E = \frac{1}{2} m\dot{r}^2 + \frac{1}{2} m r^2 \dot{\phi}^2 - \frac{k}{r}$$

$$= \frac{p_r^2}{2m} + \frac{L^2}{2mr^2} - \frac{k}{r}$$

$$\Rightarrow p_r = \sqrt{2mE - \frac{L^2}{r^2} + \frac{2k}{r}}$$

This is equal to  $n\phi h$  which gives me  $L = n\phi h$  or  $n\phi h$  cross which is the same as Bohr's condition. If we considered only orbits then we have  $p_r$  is equal to  $m\dot{r}$  is equal to 0,  $L$  is equal to  $n\phi h$  cross and the energy would be equal to one half  $m\dot{r}^2$  which will be 0 and  $\frac{1}{2} m r^2 \dot{\phi}^2$  minus  $k/r$ , and with  $m\frac{v^2}{r} = \frac{k}{r^2}$  with  $r = R$  this will give me the same answer as Bohr model.

Now, we are considering the possibility that the particle can also perform motion in  $r$  direction. So, there is an  $\dot{r}$  involved. So, this gives me the elliptical orbits and for that I have  $p_r dr$  which is non 0 which is  $m\dot{r} dr = n_r h$ . So, now, I have 2 quantum numbers  $n_r$  and  $n\phi$ . So, let us calculate this. From the energy condition  $e$  equals one half  $m\dot{r}^2$  plus one half  $m r^2 \dot{\phi}^2$  minus  $k/r$ , which is same as  $\frac{p_r^2}{2m} + \frac{L^2}{2mr^2} - \frac{k}{r}$ , I get  $p_r$  is equal to square root of  $2mE - \frac{L^2}{r^2} + \frac{2k}{r}$ , right.

(Refer Slide Time: 18:20)

$$p_r = \sqrt{2mE - \frac{L^2}{r^2} + \frac{2k}{r}}$$

$r_1$  and  $r_2$  are points when  $\dot{r} = 0 \Rightarrow p_r = 0$

$$2mE - \frac{L^2}{r^2} + \frac{2k}{r} = 0$$

$$n_r h = 2 \int_{r_1}^{r_2} \sqrt{2mE - \frac{L^2}{r^2} + \frac{2k}{r}} dr$$

$$n_r h = -2\pi \left( L - \frac{mk}{\sqrt{-2mE}} \right)$$

Keep in mind  
Bound state  
 $E < 0$

So, I have  $p_r$  is equal to  $2mE$  minus  $L^2$  over  $r^2$  plus  $2k$  over  $r$  square root.

The solve it is like this I have a  $r_1$ , I have a  $r_2$ ,  $r_1$  and  $r_2$  points where  $\dot{r}$  is equal to 0 which implies  $p_r$  is also be equal to 0. So, those can be calculated from the expression while writing  $2mE$  minus  $L^2$  over  $r^2$  plus  $2k$  over  $r$  is equal to 0. So, what one I have is therefore,  $n_r h$  would be equal to integral  $r_1$  to  $r_2$  integral of  $2mE$  minus  $L^2$  over  $r^2$  plus  $2k$  over  $r$  times 2 this integral slightly complicated. So, I will just give with the answer, the answer for this whole thing comes out to be minus  $2\pi$   $L$  minus  $mk$  sorry this is a  $m$  here, there is a  $m$  here  $mk$  over square root of minus  $2mE$  that is it. So, this is  $n_r h$  this giving you the final answer for the integral and this is what is going to determine the energy.

Now, you may wonder why these minus  $2mE$ ? Keep in mind that this is a bound state and therefore,  $E$  is less than 0. So, what we get is.

(Refer Slide Time: 20:34)

The whiteboard contains the following handwritten equations:

$$(i) \int p_{\phi} d\phi = n_{\phi} h \Rightarrow L = n_{\phi} h$$

$$(ii) \oint p_r dr = n_r h$$

$$-2\pi \left( L - \frac{mk}{\sqrt{-2mE}} \right) = n_r h$$

$$L - \frac{mk}{\sqrt{-2mE}} = -n_r h$$

$$L = n_{\phi} h$$

$$(n_{\phi} + n_r) h = \frac{mk}{\sqrt{-2mE}}$$

$$E_{n_{\phi} + n_r} = - \frac{mk^2}{2n^2 h^2} = \left( \frac{m z^2 e^4}{32 \pi^2 \epsilon_0^2 h^2} \right)$$

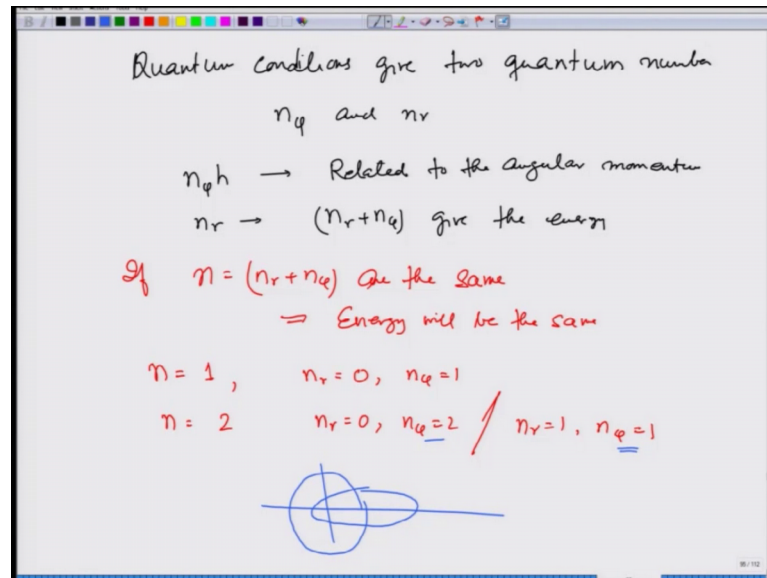

So, from the first condition integral  $p_{\phi} d\phi$  is equal to  $n_{\phi} h$ , I get  $L$  equals  $n_{\phi} h$  cross and from the second condition that integral  $p_r dr$  is equal to  $n_r h$ , I get minus  $2\pi$   $L$  minus  $m k$  over square root of minus  $2 m E$  equals  $n_r h$  and therefore,  $L$  minus  $m k$  over square root of minus  $2 m e$  is equal to  $n_r h$  cross with the minus sign or  $L$  which is  $m \phi h$  cross, if I substitute that I get  $n_{\phi} h$  plus  $n_r h$  cross is equal to  $m k$  over square root of minus  $2 m e$  or  $e$  equals  $m \phi$  plus  $n_r$  equals  $k$  square over  $2$ , there will be an amount of  $n$  square  $h$  cross square with the minus sign which is same as  $m z$  square  $e$  raise to  $4$  over  $32 \pi$  square  $\epsilon_0$  square  $h$  cross square to the minus sign  $1$  over times  $n$  over  $m$  square.

(Refer Slide Time: 22:35)

The image shows a whiteboard with handwritten mathematical derivations. At the top, the energy level formula is given as  $E_n = -\left(\frac{m z^2 e^4}{32 \pi^2 \epsilon_0^2 h^2}\right) \frac{1}{n^2}$ . Below this, it is noted that  $n = (n_\phi + n_r)$ . A note says "By Bohr model  $n_\phi = 0 \Rightarrow$  Zero angular momentum". Then, two sets of quantum numbers are listed:  $n_\phi = 1, 2, 3, \dots$  and  $n_\theta = 0, 1, 2, \dots$ , with a bracket indicating  $n = n_\phi + n_\theta$ . The final energy formula is circled:  $E_n = -\frac{13.6 z^2}{n^2} \text{ eV}$ . At the bottom, a note states "The Wilson-Sommerfeld quantum conditions give TWO QUANTUM NUMBERS  $n_\theta$  &  $n_r$ ".

So, we getting an energy  $e$  which is equal to minus  $m z$  square  $e$  raise to 4 over 32 pi square epsilon 0 square  $h$  cross square 1 over  $n$  square, let me call this  $n$  where  $n$  is  $n$  phi plus  $n r$ . Now by Bohr model or also because  $n$  phi equal 0 would imply 0 angular momentum how to exclude that and call  $n$  phi equals 1, 2, 3 and so on and  $n$  theta equal 0, 1, 2 and so on and  $n$  equals  $n$  phi plus  $n$  theta and. So, energy  $E_n$  is given by this number which is same as the Bohr answer minus 13.6  $z$  square over  $n$  square electron volts you can calculate this number in that comes out to be, which is exactly the same answer as the Bohr model; what it gives you; however, are now let us just analyze this the Wilson quantum conditions give 2 quantum numbers and phi and  $n r$ .

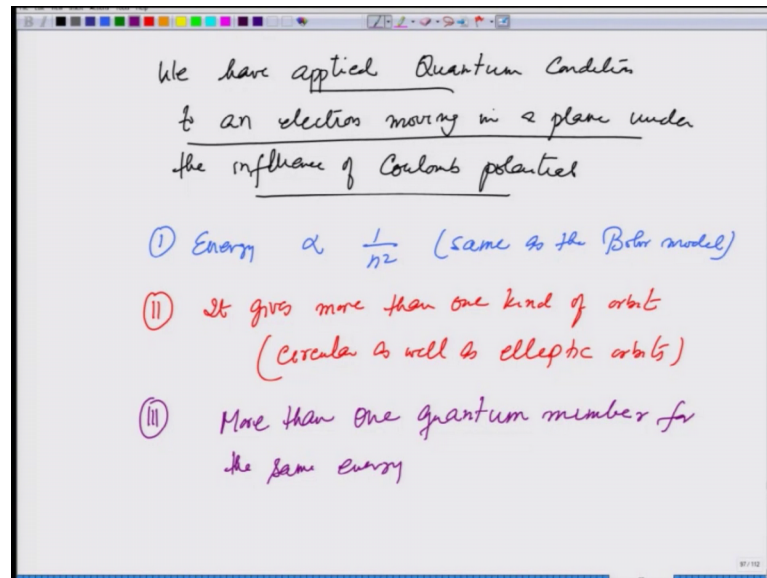

(Refer Slide Time: 24:42)

So, quantum conditions give 2 quantum numbers  $n_\phi$  and  $n_r$  and let us see; what they mean.  $n_\phi h$  is related to the angular momentum and  $n_r$  the such that  $n_r$  plus  $n_\phi$  give the energy. So, if  $n$  equals  $n_r$  plus  $n_\phi$  are the same energy will be the same; however, these are 2 different orbits for example, suppose  $n$  is equal to one I could have  $n_r$  equals 0 and  $n_\phi$  equals 1. Suppose  $n$  equals 2, I could have  $n_r$  equals 0  $n_\phi$  equals 2 or  $n_r$  equals 1 and  $n_\phi$  equals 1 they both give the same energy.

Now, what kind of orbits would they be if  $n_\phi$  is 2, I would expect this to have less eccentricities and that could be a circular orbit;  $n_\phi$  is one that is less of an angular momentum. So, it could be an elliptic orbit. So, what we have now introduce generalize the idea of these orbits of electrons moving in a plane when they are moving under the influence of coulomb potential through Wilson Sommerfeld quantization conditions now will a more orbits then one that have the same energy; however, different quantum numbers.

(Refer Slide Time: 26:57)

So, to conclude this lecture, we have applied quantum conditions to an electron moving in a plane under the influence of coulomb potential and what do we find one energy comes out to be proportional to 1 over n square same as the Bohr model. More important however, is it gives more than one kind of orbit and circular as well as elliptic orbits and it introduces the idea of more than one quantum number for the same energy more than one quantum number means they could be more orbits than one orbit which has the same energy and in this case they happened to be circular elliptic orbits of different eccentricities.
