Lecture - 02
General nature of the correspondence principle

Let us take a harmonic oscillator.

(Refer Slide Time: 00:16)

$E = \frac{1}{2} k A^2 = \frac{1}{2} m \omega^2 A^2$

Use J for action because I am using A for amplitude

$$J = 2 \int_{-A}^A p dx = 4 \int_0^A p dx$$

$$\frac{p^2}{2m} = E - V(x) \quad \Rightarrow \quad p = \sqrt{2m(E - V(x))}$$

$$J = 4 \sqrt{2m} \times \sqrt{\frac{m}{2}} \cdot \omega \int_0^A \sqrt{A^2 - x^2} dx$$

$$= 4 m \omega \int_0^A \sqrt{A^2 - x^2} dx$$

$$= \frac{\pi}{4} A^2 \times 4 m \omega = \pi m \omega A^2$$

The energy for this is suppose this is oscillating with amplitude A , this is A , energy is given as one half $k A^2$ which is one half mass of the particle $\omega^2 A^2$ square. Let us write this in terms of action, let me use J for action because I am using A for amplitude. So, J is nothing but integral minus A to A $p dx$ times 2 which is same as 4 times 0 to A $p dx$ which is nothing but 4 times 0 to A square root of total energy one half $m \omega^2 A^2$ square minus potential energy one half $m \omega^2 x^2$ square thus the kinetic energy divided by. So, p^2 over $2m$, p^2 over two m is nothing but $E - V(x)$. So, I am going to have square root of $2m$ also here does the action.

So, action J comes out to be 4 times square root of $2m$ times what will come out is m square root of m over 2 times ω and inside I have 0 to a square root of a square minus x^2 square dx . So, this is nothing but $4 m \omega$ times 0 to A square root of a square minus x^2 square dx . This integral is easy to calculate and its value comes out to be π by 4

A square times 4 m omega which is then become therefore, pi m omega A square that is the value.

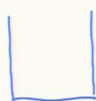

(Refer Slide Time: 02:47)

$$E = \frac{1}{2} m \omega^2 A^2$$

$$J = \pi m \omega A^2$$

$$\frac{E}{J} = \frac{\omega}{2\pi} \Rightarrow E = 2J\nu$$

$$\boxed{\left(\frac{\partial E}{\partial J}\right) = \nu}$$

$$E = \frac{1}{2} m v^2 = \frac{p^2}{2m}$$

$$J = \oint p dx = 2Lp \Rightarrow p = \frac{J}{2L}$$

$$E = \frac{J^2}{8mL^2} \Rightarrow \left(\frac{\partial E}{\partial J}\right) = \frac{J}{4mL^2} = \nu$$

The recall that energy E is one half m omega square A square, J has come out to be pi m omega A square. So, this gives you E by J equals omega over 2 pi or E equals omega over 2 pi is a frequency of oscillation times J.

So, d E d J is nu I shown you through one example. Let us take another example let us take particle in a box. Particle in a box the energy classical is one half m v square or also p square over 2 m, and the action is p d x over the entire period and this comes out to be 2 LP. So, P is nothing but J over 2L and therefore, the energy comes out to be J square over 4 m L square, which gives me d E d J to be equal to J over 4 m L square which is 2L J is 2L p; so 2L p over 4 m L square.

(Refer Slide Time: 04:34)

The whiteboard contains the following content:

- A square box representing a particle in a box.
- A circular path with radius R and arrows indicating clockwise motion.
- Equation: $\frac{\partial E}{\partial J} = \frac{2Lp}{4mL^2} = \frac{v}{2L} = \nu$
- Equation: $E = \frac{L^2}{2mR^2} + V(R)$
- Equation: $J_\phi = \oint L d\phi = 2\pi L$
- Equation: $L = \frac{J_\phi}{2\pi}$
- Equation: $E = \frac{J_\phi^2}{8\pi^2 m R^2} + V(R)$
- Equation: $\left(\frac{\partial E}{\partial J_\phi}\right) = \frac{J_\phi}{4\pi^2 m R^2} = \frac{m v R}{4\pi^2 m R^2} = \frac{1}{2\pi} \left(\frac{v}{R}\right)$

So, what we have found in particle in a box dE/dJ is nothing but $2Lp$ over $4mL^2$ which is nothing but p over m , p over m is the velocity divided by $2L$ which is again the frequency of oscillation ν .

It is the two examples; third example let us take example number 3 where a particle is going around the central potential. In this case the energy is suppose this radius is fixed energy has nothing but L^2 where L is the angular momentum divided by $2mR^2$ plus whatever potential energy $V(R)$, and recall that action J for this motion let us call it J_ϕ is equal to integral $L d\phi$ which is $2\pi L$. So, L is nothing but J_ϕ over 2π and therefore, I can write the energy E as L^2 which is J_ϕ^2 divided by $8\pi^2 m R^2$ plus whatever $V(R)$.

Since there is no V , so $V(R)$ remains fixed and therefore, dE/dJ_ϕ is nothing but J_ϕ over $4\pi^2 m R^2$ and let us write J_ϕ in terms of the angular momentum which is $m v R$ times 2π divided by $4\pi^2 m R^2$, and let us cancel a few terms this m cancels this cancel one of the R , so this R cancels and let us cancel 2π . So, this 2π cancels with this $4\pi^2$ and you get 2π which is nothing but v over R $1/2\pi$ which is ω over 2π which is ν again.

(Refer Slide Time: 07:05)

$$\left(\frac{\partial E}{\partial J}\right) = \nu_{\text{classical}} \leftarrow$$

Quantum mechanically : $n \rightarrow \infty \quad \left(\frac{\Delta E}{h}\right) \rightarrow \tau \nu_{\text{class}}$

<p>Classical</p> $\left(\frac{\partial E}{\partial J}\right) = \nu_{\text{class}}$	}	<p>Quantum</p> $n \rightarrow \infty \quad \frac{\Delta E}{h} = \tau \nu_{\text{classical}}$
--	---	--

$$\Delta E = E_n - E_{n-\tau} = (\text{for large } n)$$

$$= \left(\frac{\partial E}{\partial J}\right) \Delta J$$

$$J: nh \rightarrow (n-\tau)h \Rightarrow \Delta J = \tau h$$

So, what I have shown you is that this result dE/dJ is equal to $\nu_{\text{classical}}$ through examples I have shown you that this is true and quantum mechanically, what we have shown is that as n approaches to large value $\Delta E/h$ goes to $\tau \nu_{\text{classical}}$.

Some two results we have two results classical dE/dJ equals $\nu_{\text{classical}}$, and here quantum n tending to infinity $\Delta E/h$ is equal to $\tau \nu_{\text{classical}}$. Now you are going to (Refer Time: 08:15) two the wave we do it is like this, I know ΔE is $E_n - E_{n-\tau}$ which can be written for large n , I can write this as $\partial E / \partial J \Delta J$, because J is going to be very large if you change τ by very small number you can effectively write as if the whole thing has gone in to a continue.

Change one or two in presence of an infinitely large number is very small, and when I making a jump from n th level to $n - \tau$ level, my J goes from nh to $(n - \tau)h$, which implies that ΔJ is τh .

(Refer Slide Time: 09:30)

$$\Delta E = \left(\frac{\partial E}{\partial J}\right) \cdot \Delta J = \left(\frac{\partial E}{\partial J}\right) \tau h$$

$$\frac{\Delta E(n \rightarrow n-\tau)}{h} = \tau \nu_{\text{classical}}$$

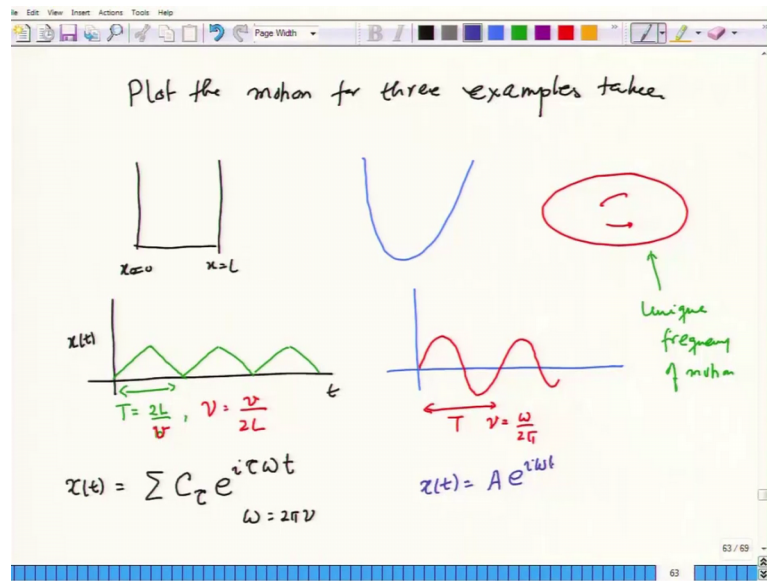

Show that result of $\nu_{n, n-\tau} = \tau \nu_{\text{classical}}$ is not a coincidence but a fundamental principle

CORRESPONDENCE PRINCIPLE: for large quantum numbers, quantum results go over to the corresponding classical results

So, I have ΔE is equal to $\frac{\partial E}{\partial J} \Delta J$, which goes over to $\frac{\partial E}{\partial J} \tau h$ or $\frac{\Delta E(n \rightarrow n - \tau)}{h}$ is nothing but $\tau \nu_{\text{classical}}$. So, what we have shown is that the result of $\nu_{n, n - \tau} = \tau \nu_{\text{classical}}$ is not a coincidence, but a fundamental result principle and this is known as the correspondence principle. Let me write this the correspondence principle as stated by Bohr. This is observed in terms of frequency, but he is saying now that for large quantum numbers quantum results go over to the corresponding classical results.

Therefore I can hope if I know the classical results well, that I can go back and go for a small n values and anticipate what would happen in quantum theory. Let me just end this lecture by telling what implications does it have.

(Refer Slide Time: 11:45)

So, if I plot the motion for three examples taken. So, I will take this particle in a box, I will take the harmonic oscillator and I will take this electron going around in a circle here. If I plot x versus t between 0 and x equals L the motion looks like this, where this time is equal to $2L$ over v or the frequency corresponding frequency $2L$ over v corresponding frequencies ν over $2L$. In the second case motion looks harmonic and this time is the time period and frequency is ω over 2π it contains one frequency, and here in the third case also this is the circular motion this is the unique frequency of motion.

Let me explain this through Fourier series. In the first case x versus t would be given as summation some coefficient for τ $e^{i\tau\omega t}$, where ω is $2\pi\nu$ that is the fundamental frequency, but because it is not purely harmonic, it contains many more harmonics. In the second case x versus t is purely harmonics. So, this is some amplitude $A e^{i\omega t}$, plus another sub amplitude $A_{\tau} e^{-i\tau\omega t}$.

(Refer Slide Time: 13:59)

$x(t) = R \cos \phi$
 $= R \cos \omega t$
 $y(t) = R \sin \omega t$

The motion contains frequency $\frac{v}{2L}$ & its higher harmonics.

The motion contains only one frequency $\omega = \sqrt{\frac{k}{m}}$
 $v = \frac{\omega}{2\pi}$

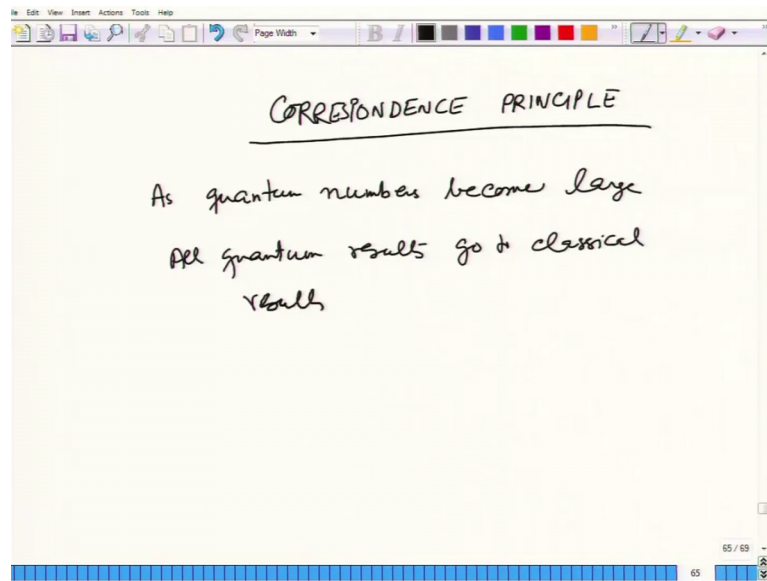

x & y vary with one frequency
 $\frac{L}{mR^2} = \omega$ $v = \frac{\omega}{2\pi}$

In the third case where this is the circular motion x t would be given as the radius R cosine of ϕ which is R cosine of ωt this is one frequency, and y t will be given as r sin of ωt .

So, in the first case where the particle is doing a particle in a box moving back and forth, the motion contains frequency v over $2L$ and its higher harmonics. So, if this particle what to radiate it will contain all these frequencies v over $2L$ and higher harmonics. On the other hand in this case the motion contains only one frequency. So, if it (Refer Time: 15:10) to radiate we will radiate that particular frequency ω which is square root of k over m or ν equals ω over 2π , and in the third case again x and y vary with one frequency, which we can write as L the angular momentum over $m R^2$ equals ω or ν equals ω over 2π and in this case also the particle classically radiates only one frequency.

Using these and making correspondence with the quantum results I will show you in next lecture how this leads to selection rules. So, to conclude this lecture I will just again write the correspondence.

(Refer Slide Time: 15:55)

Principle which will be guiding principle for or next two or three lectures, is that as quantum numbers become large all quantum results go to a classical results.
