**The stationary-state Schrodinger equation and its solution for particle in a box**

(Refer Slide Time: 00:17)

So, I am introducing you to the idea of a particle having a wave associated with it. And in the previous lecture I gave it a notation  $\psi(x,t)$ . This is pronounced psi, it is pronounced as psi, it is a Greek letter. And we want to now discover what is the equation satisfied by  $\psi(x,t)$ . So, there is a wave associated. We do not know what that amplitude means, how can we say what we still want to discover what is the equation satisfied by. And this discovery was made by Erwin Schrodinger.

Who proposed an equation for psi and right now I will focus on time-independent psi, now stationary psi. Right now I will focus on stationary  $\psi(x,t)$ , but a discovery of Schrodinger was made for  $\psi(x,t)$  both stationary as well as time-independent. Now this I want to give a word of caution, and the caution is that this equation is discovered, it exists somewhere and is discovered. And therefore, it is a fundamental equation. So, this is what I am telling you and the caution is do not think that it can be derived. It can be discovered by looking at it from different means, it can be justified, the ultimate test is experiment. The ultimate test for the equation is matching of results with experiments.

So, he propose this equation I discovered this now we say discovered because once it is discovered it all the reserves that he found from this to matching with experiments, but it is a fundamental equation it can be discovered by different means, but it is a fundamental equation it cannot be derived from anything else. So, please be aware of that lot of people say derived Schroedinger equation that is a wrong statement to make. So, we will want to now kind of arrive at this equation and discover whether it is right or what. So, having given this background what I want to focus on now is this stationary state Schroedinger equation.

(Refer Slide Time: 04:01)

Stationary state Schrödinger Equation  
(Time-independent Schrödinger Equation)

Stationary wave  $\psi(x,t) = \psi(x) T(t)$

$T(t) = \sin \omega t / e^{-i\omega t}$

Time part of a stationary wave was a pure single frequency part (frequency =  $\omega$ )

Stationary waves in Schrödinger's theory

$$\omega = E/h = \frac{2\pi E}{h}$$

$$\psi(x,t) = \psi(x) e^{-iEt/h}$$

Or what is also known as time independent Schroedinger equation. Let me this give you a little background if you recall from our discussion on the waves a stationary wave was something that had now I will talk in terms of psi x t. Space part, let us write this as psi x and a time part and they were separated. And time part for a stationary wave was of the form sin omega t or e raise to minus I omega t and take it is real or imaginary part. So, time part of a stationary wave was a pure single frequency part right. And that was frequency or angular frequency was omega in the same manner the stationary waves in Schroedinger's theory will have a pure omega which will be given as E over h cross which is same as 2 pi E over h ok.

So, psi x t again is going to be written as some psi of x e raise to minus I e t over h cross. And we are looking for the equation for this psi x part.

(Refer Slide Time: 06:37)

$$\left( \frac{d^2 \psi}{dx^2} + k^2 \psi \right) = 0 \quad k = \frac{\omega}{v}$$
$$\psi(x)$$
$$k_{\text{material wave}} \quad k_{\text{particle}} = \frac{2\pi}{\lambda} = \frac{2\pi}{h/p}$$
$$k_{\text{particle}} = \frac{2\pi p}{h} = \frac{p}{\hbar}$$
$$k^2 = \frac{p^2}{\hbar^2} = \frac{2m(E - V(x))}{\hbar^2}$$
$$\frac{d^2 \psi}{dx^2} + \frac{2m}{\hbar^2} (E - V(x)) \psi = 0$$

Recall from the stationary waves and I am focusing on one dimension.  $\frac{d^2 \psi}{dx^2} + k^2 \psi = 0$  when  $\psi$  depends only on  $x$  and there is a pure wave. And  $k$  was nothing but  $\omega/v$ . Let us go back to that (Refer Time: 07:04). So, can I argue from here that a similar equation exists for material waves. So, let us see what is  $k$  for material wave. Or  $k$  for a particle, it is given as  $2\pi/\lambda$ . Which is nothing but  $2\pi/\lambda$  is  $h$  divided by  $p$ . So, I can write  $k_{\text{particle}}$  is  $2\pi p/h$  or  $p/h$ . And therefore,  $k^2$  is going to be  $p^2/h^2$ , and for a particle of energy  $E$   $p^2$  is nothing but  $2m(E - V(x))$  divided by  $h^2$ , that is  $p^2$ .

Let us substitute this here. When I substitute this here I am going to get  $\frac{d^2 \psi}{dx^2} + \frac{2m}{\hbar^2} (E - V(x)) \psi = 0$ . Can this be equation for the particle waves?

(Refer Slide Time: 08:37)

$$-\frac{\hbar^2}{2m} \frac{d^2\psi}{dx^2} + V(x)\psi(x) = E\psi(x)$$

$$\psi(x,t) = \psi(x) e^{-iEt/\hbar}$$

Schrödinger Equation for stationary states  
 To be solved with boundary condition

↓  
 Boundary conditions are satisfied with only  
 Energies  $E_n$  (Eigen energies)

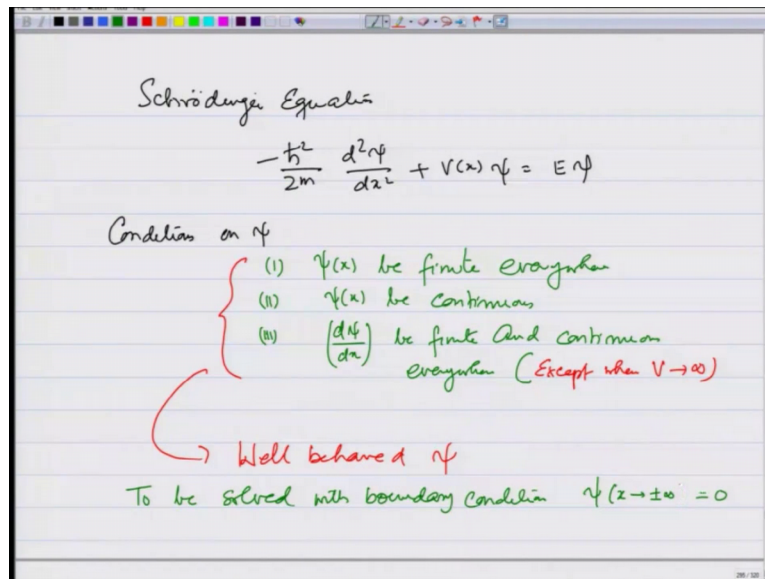

$\psi(x)$  satisfy certain condition

So, this by manipulation gives you minus  $\hbar$  cross square over  $2m$   $d^2\psi$  over  $dx^2$  plus  $V(x)\psi(x)$  equals  $E\psi(x)$ . This is what Schroedinger proposed and the time dependence of this  $\psi(x,t)$  would be equal to  $\psi(x)$  that will be calculated from the equation above times  $e$  raised to minus  $iEt$  over  $\hbar$  cross. So, this is a stationary wave oscillating with frequency  $e$  by  $\hbar$  cross. Can this be the equation for the waves test? As I said earlier is the solution of this and comparison with the experiments or earlier known results.

So, we will solve this and try to see if this gives the results that were known earlier. And if the match with the experiments. So now, this equation is to be solved. So, this is known as the Schroedinger equation, for stationary states. And as I said earlier this is to be solved with boundary conditions. And when you solve a problem with boundary conditions if you recall again from the example of string in my lecture on waves, boundary conditions means that the boundary conditions are satisfied with only certain energies  $E_n$  and these will be known as Eigen energies. And these will represent the stationary state energy of the system for example, in hydrogen atom they will give you the energy is determined earlier.

So, we have to check that, and we also demand that  $\psi(x)$  satisfy certain conditions.

(Refer Slide Time: 11:12)

So, the equation we are saying the Schroedinger equation is minus h cross square over 2 m, d 2 psi over d x square plus v x psi equals E psi. And conditions on psi are number 1, psi x be finite everywhere number 2 psi x be continuous. Number 3 d psi by d x be finite and continuous everywhere. Let me write a warning here except when v goes to infinity or v is not well behaved. So, all these 3 things I would say are the well behaved psi. So, we are going to demand that the solutions be finite everywhere psi be continuous everywhere and d psi by d x be continuous and finite everywhere. So, that the second derivative can be also taken.

So, this is and this is to be solved with boundary conditions. And the boundary condition is going to be as we said earlier that wave function wherever it is finite there is a particle is to be found there. So, wherever particle is not to be found and; that means, generally x tend into plus or minus infinity will demanded psi be 0 or looking at the physical situation psi should vanish wherever the particle is not to be found at all, otherwise is finite continuous and is derivative finite in continuous. It is 3 dimensional generalization can also be written.

(Refer Slide Time: 13:32)

$$-\frac{\hbar^2}{2m} \frac{d^2\psi}{dx^2} + V(x)\psi = E\psi$$

3d:

$$-\frac{\hbar^2}{2m} \nabla^2 \psi(\vec{r}) + V(\vec{r})\psi(\vec{r}) = E\psi(\vec{r})$$

$$-\frac{\hbar^2}{2m} \nabla^2 \psi(x,y,z) + V(x,y,z)\psi(x,y,z) = E\psi(x,y,z)$$

Solve the Schrödinger Equation for particle in a box

$$-\frac{\hbar^2}{2m} \frac{d^2\psi}{dx^2} = E\psi \quad 0 \leq x \leq L$$

$$\psi(x=0) = 0$$

$$\psi(x=L) = 0$$

So, the one dimensional equation is minus  $\hbar^2$  over  $2m$  times the second derivative of  $\psi$  over  $x$  square plus  $V(x)\psi$  equals  $E\psi$ . The 3 dimensional in generalization is going to be minus  $\hbar^2$  over  $2m$  times the Laplacian of  $\psi$  plus  $V(\vec{r})\psi$  equals  $E\psi$  and it is going to be a function of  $\vec{r}$ ; that means,  $x$ ,  $y$  and  $z$  plus  $V(x,y,z)\psi$  equals  $E\psi$ .

Let me write it in terms of  $x$ ,  $y$  and  $z$  also minus  $\hbar^2$  over  $2m$  times the Laplacian of  $\psi$  of  $x$ ,  $y$  and  $z$  that is what that  $\vec{r}$  vector means plus  $V$  as the function of  $x$ ,  $y$  and  $z$  times  $\psi$  equals  $E\psi$ , this is going to be the equation. Now let us solve this for a simple system. Solve the Schrödinger equation for particle in a box. And this solution we have already obtained earlier from Wilson Sommerfeld quantization condition now we are going to solve it is Schrödinger equation and see what answer it gives. In this case what we are going to have is a box in which the potential is infinite outside the box, and potential is 0 inside let us say this is  $x=0$  to  $x=L$  and the particle is moving around here.

So, the Schrödinger equation is that minus  $\hbar^2$  over  $2m$  times the second derivative of  $\psi$  over  $x$  square plus  $V$  is 0 is equal to  $E\psi$  for  $x$  between 0 and  $L$ . And  $\psi(x=0) = 0$  that is the boundary condition because beyond  $x=0$  a particle cannot exist potential is infinity and therefore, any finite energy particle cannot be there and  $\psi(x=L) = 0$ . So, these are the boundary conditions, let us see what the solution is like.

(Refer Slide Time: 15:57)

$$-\frac{\hbar^2}{2m} \frac{d^2\psi}{dx^2} = E\psi$$

$$\frac{d^2\psi}{dx^2} + \frac{2mE}{\hbar^2} \psi = 0$$

$$E > 0 \quad \psi'' + k^2 \psi = 0 \quad k^2 = \frac{2mE}{\hbar^2}$$

$$\psi(x) = A \sin kx + B \cos kx$$

$$\psi(0) = 0 \Rightarrow B = 0$$

$$\psi(L) = 0 \Rightarrow A \sin kL = 0 \Rightarrow k_n = \frac{n\pi}{L}$$

$$k_n^2 = \frac{n^2 \pi^2}{L^2} = \frac{2mE_n}{\hbar^2} \Rightarrow E_n = \frac{n^2 \hbar^2 \pi^2}{2mL^2}$$

$$E_n = \text{Eigen energy}$$

So, I am solving for particle in a box  $V \rightarrow \infty$  outside, particle is inside and the equation is  $-\frac{\hbar^2}{2m} \frac{d^2\psi}{dx^2} = E\psi$ . And therefore,  $\frac{d^2\psi}{dx^2} + \frac{2mE}{\hbar^2} \psi = 0$ . And for  $E > 0$  this is very simple to solve call this  $k^2$ . So, this equation becomes  $\psi'' + k^2 \psi = 0$ , where  $k^2 = \frac{2mE}{\hbar^2}$  and this solution we have already know from the string solution.

$\psi(x)$  is going to be  $A \sin kx + B \cos kx$ . And  $\psi(0) = 0$  implies  $B = 0$ .  $\psi(L) = 0$  implies  $A \sin kL = 0$ . And therefore, this boundary condition is satisfied only for  $k_n = \frac{n\pi}{L}$ . And therefore,  $k_n^2$  which is  $\frac{n^2 \pi^2}{L^2}$  is equal to  $\frac{2mE_n}{\hbar^2}$  and this immediately tells me that  $E_n$  is equal to  $\frac{n^2 \hbar^2 \pi^2}{2mL^2}$ . Which is the same answer as obtained earlier by Wilson Sommerfeld quantization conditions. So, you see Schrodinger equation gives me the same answer except, now that I have solved it now I have obtained that answer through the solution of a wave equation. And the energies that I stationary energies appear as Eigen energy.

So,  $E_n$  is an Eigen energy, it is only for these energies that the boundary conditions is satisfied properly. So, in the wave picture it is the boundary condition that gives you those discrete Eigen energies. Because only for those energy is the boundary condition is satisfied. What about the wave function?

(Refer Slide Time: 18:28)

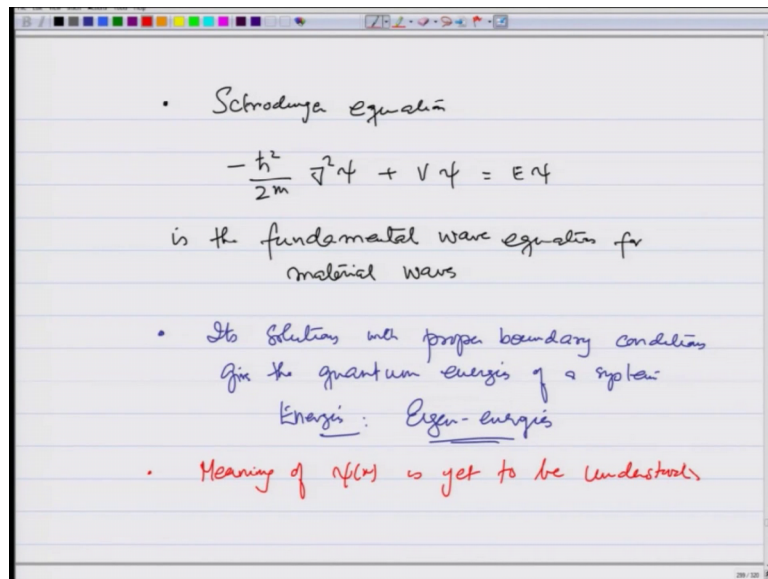

So, if I look at  $E_n$  which is  $\hbar^2 n^2 \pi^2$  over  $2mL^2$  it is going to be  $n=1$  is going to give me  $\hbar^2 \pi^2$  over  $2mL^2$  energy. And the wave function is going to be  $\sin\left(\frac{\pi}{L}x\right)$  times a constant  $A$  which we have not determined so far. For higher  $n$ s it is going to be  $\sin\left(\frac{n\pi}{L}x\right)$ . So,  $E_n$  and the corresponding wave function  $\psi(x)$  is some constant  $A \sin\left(\frac{n\pi}{L}x\right)$ , how do these wave functions look so?

Let me plot this here. For  $n=1$  it looks exactly the same as a string wave function. This is  $n=1$ , for  $n=2$  is wave function looks like this. This is  $n=2$ . For  $n=3$  this wave function looks like this. So, you see as we go to higher and higher energies, wave function bends more and more and that makes sense, because  $\lambda$  becomes smaller and smaller, so it gains more kinetic energy. So, you can see right away that more wiggles more turning off the wave function around means higher kinetic energy. And the solutions are exactly like the wave solution for a string. So, one should not feel really scared about you know solving the Schrodinger equation it is a wave equation like equation on a string. And eigenvalues are now related to the stationary state energies of a quantum system. With that introduction and simple example I conclude this lecture by stating that number 1.

(Refer Slide Time: 20:19)

Schrodinger equation minus  $\hbar^2$  over  $2m$  del square psi plus  $V$  psi equals  $E$  psi is the fundamental wave equation for material. Waves number 2; it is solutions with proper boundary conditions give the quantum energies of a system.

These energies are known as the Eigen energies. I have introduced the idea of eigenvalues earlier in the wave lecture. And meaning of psi is yet to be understood.
