Lecture – 01

Equivalence of the Heisenberg and the Schroedinger formulations – Mathematical preliminaries

(Refer Slide Time: 00:15)

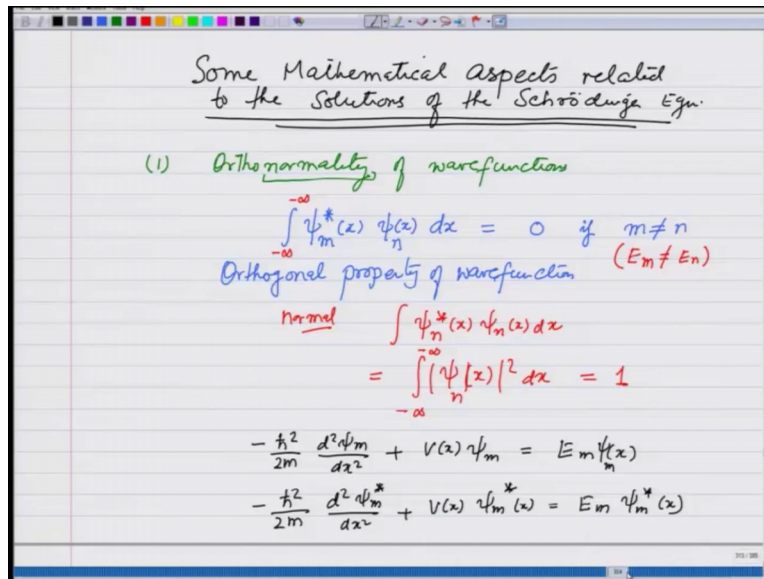

What you have learnt so far in quantum mechanics is Heisenberg's approach to quantum mechanics, which essentially involved matrices to represent dynamical quantities. And the equation of motion was same as classical equation. And quantum condition was represented as $p x$ minus $x p$ equals h cross over I the identity matrix. I we have also learnt another approach which is Schroedinger's approach which is very, very different on the surface from Heisenberg's approach, and what happens in this approach is the particle has a wave function $\psi(x)$ associated with it. Number 2 there is a wave equation known as the Schroedinger's equation, and 3 the Eigen values determined by the boundary condition give the energies.

So, these 2 are very different approaches, but what you learnt is that for simple harmonic oscillators both give the same answers. Is it mere coincidence that both give the same answer or is there a deeper meaning is there any connection? Or are these 2 approaches the same they are just represented in a different way? What we are going to do in the next 2 lectures is learned that actually Heisenberg's approach to quantum mechanics and

Schrodinger's approach to quantum mechanics are one and the same thing. And this will also teach about how quantities are represented in Schrodinger's approach. For example, we will write the operators for the momentum and so on, and all that requires a little bit of mathematical preparation which I am going to do in this lecture.

So, this lecture is essentially devoted to some mathematical aspects related to the solutions of the Schrodinger equation.

(Refer Slide Time: 03:38)

So, first in that I want to talk about is the ortho normality of wave functions. And let me explain normality is the property that we in first ortho means perpendicular. So, this first I am going to talk about of the ortho behavior or the perpendicular behavior of the 2 way function. So, what we mean by that is, if there is a wave function $\psi_m x$ and I am going to restrict myself to one dimension. Idea is to give you the concepts one dimension makes it easy. $\psi_m^* \psi_n$ product where m and n are 2 indices for the energy level integrated over is equal to 0 if m is not equal to n . So, this is what I am going to call the orthogonal property of wave function.

I am going to explain in a bit what we mean when we say m is not equal to n , what it would amount to is that if the energy related to m th level is not equal to energy related to n th level. So, this is the orthogonal property of wave function which is going to be satisfied. Normal means and that I will explain the second points, normal means that for the same n $\psi_n^* \psi_n dx$ which is equal to integral of mode of ψ_n

$x^2 dx$ is going to be one. We choose the coefficient the constant, we choose the constant in front of ψ and such that it has integrated to 1. And the integration is carried to all over the space minus infinity to infinity.

Similarly, in orthogonal behavior is also minus infinity to infinity. So, normal part I will come to normality we in force. Orthogonality that these wave functions are orthogonal in the sense of the way I have explained above it follows. So, let us prove that. So, to prove this let us take the Schrodinger's equations $\frac{d^2 \psi_m}{dx^2} + V(x) \psi_m = E_m \psi_m$. If I take it is complex conjugate all the real quantities remain the same ψ_m^2 over $2m$ $\frac{d^2 \psi_m^*}{dx^2} + V(x) \psi_m^* = E_m \psi_m^*$. So, we have just written a Schrodinger equation for ψ_m^* for it is complex conjugate as well as the wave function itself.

(Refer Slide Time: 07:35)

The image shows a handwritten derivation on a digital whiteboard. The text reads: "Prove if $E_m \neq E_n$ then $\int \psi_m^*(x) \psi_n(x) dx = 0$ ". Below this, the Schrodinger equation for ψ_n is written: $-\frac{\hbar^2}{2m} \frac{d^2 \psi_n}{dx^2} + V(x) \psi_n = E_n \psi_n$. The equation is then multiplied by ψ_m^* and integrated from $-\infty$ to ∞ . The result is $E_n \int \psi_m^* \psi_n dx$. A second equation is derived for ψ_m^* : $-\frac{\hbar^2}{2m} \frac{d^2 \psi_m^*}{dx^2} + V(x) \psi_m^* = E_m \psi_m^*$. This is multiplied by ψ_n and integrated from $-\infty$ to ∞ , resulting in $E_m \int \psi_m^* \psi_n dx$. The two equations are then subtracted, leading to $(E_n - E_m) \int \psi_m^* \psi_n dx = 0$. Since $E_n \neq E_m$, it follows that $\int \psi_m^* \psi_n dx = 0$.

So now I am going to prove that if what we have to prove, now prove if E_m is not equal to E_n then integration $\psi_m^* \psi_n dx$ is equal to 0. So, let us write the equation for n th level which is $-\frac{\hbar^2}{2m} \frac{d^2 \psi_n}{dx^2} + V(x) \psi_n = E_n \psi_n$, multiply by ψ_m^* from the left integrate over dx this is what operation I am carrying out. So, that this equation can be written as $-\frac{\hbar^2}{2m} \int \psi_m^* \frac{d^2 \psi_n}{dx^2} dx + \int \psi_m^* V(x) \psi_n dx = E_n \int \psi_m^* \psi_n dx$. Let me

simplify the first term this term, which I can write as minus h cross square over 2 m integration minus infinity to infinity, d by d x of psi m star d psi n by d x, plus h cross square is integrated over x over 2 m integration d psi m star over d x d psi n over d x d x.

The first term can be integrated fully and since psi and their derivatives all go to 0 as x tends to infinity this term is going to be 0. And therefore, the first term can be written only as plus h cross square over 2 m integration from minus infinity to infinity, d psi m star d x d psi n d x d x. And therefore, I can write the Schroedinger equation after this integration as h crosses square over 2 m Integration minus infinity to infinity d psi m star over d x d psi n over d x integrated over plus minus infinity to infinity.

(Refer Slide Time: 10:23)

The image shows a digital whiteboard with handwritten mathematical derivations. At the top, the equation is written as:

$$\frac{\hbar^2}{2m} \int_{-\infty}^{\infty} \left(\frac{d\psi_m^*}{dx} \right) \left(\frac{d\psi_n}{dx} \right) dx + \int_{-\infty}^{\infty} \psi_m^*(x) V(x) \psi_n(x) dx = E_n \int_{-\infty}^{\infty} \psi_m^* \psi_n dx \quad (1)$$

Below this, the first term is expanded:

$$-\frac{\hbar^2}{2m} \frac{d^2\psi_m^*}{dx^2} + V(x) \psi_m^*(x) = E_m \psi_m^*(x)$$

A red bracket indicates that this equation is multiplied by $\psi_n(x)$ and integrated from $-\infty$ to ∞ :

$$-\frac{\hbar^2}{2m} \int_{-\infty}^{\infty} \frac{d^2\psi_m^*}{dx^2} \psi_n(x) dx + \int_{-\infty}^{\infty} \psi_m^*(x) V(x) \psi_n(x) dx = E_m \int_{-\infty}^{\infty} \psi_m^* \psi_n dx \quad (11)$$

Finally, the second term of the integral is simplified using integration by parts:

$$+\frac{\hbar^2}{2m} \int_{-\infty}^{\infty} \frac{d\psi_m^*}{dx} \cdot \frac{d\psi_n}{dx} dx \quad (11)$$

Psi m star x v x psi n x d x equals E n psi m star square minus infinity to infinity psi n d x.

Let me now write the equation for psi m star d 2 psi m star d x plus v x psi m star x equals E m psi m star x this I had did in earlier. Now what I am going to do is multiply it from the right side by psi n x and integrate minus infinity to infinity d x, So that this equation now becomes minus h crosses square over 2 m integration minus infinity to infinity, d psi m star over d x square psi n x d x plus integration minus infinity to infinity, psi m star x v x psi n x d x equals E m integration minus infinity to infinity psi m star psi n d x. I can again show by the same trick as I did earlier, that this term is equal to plus h crosses square over 2 m integration minus infinity to infinity d psi m star over d x d psi n

over dx . You do exactly the same thing you take one dy dx out and then expand this.

(Refer Slide Time: 12:41)

$$\frac{\hbar^2}{2m} \int_{-\infty}^{\infty} \frac{d\psi_m^*}{dx} \frac{d\psi_n}{dx} dx + \int_{-\infty}^{\infty} \psi_m^*(x) V(x) \psi_n(x) dx = E_n \int_{-\infty}^{\infty} \psi_m^* \psi_n dx \quad (1)$$

$$\frac{\hbar^2}{2m} \int_{-\infty}^{\infty} \frac{d\psi_m^*}{dx} \frac{d\psi_n}{dx} dx + \int_{-\infty}^{\infty} \psi_m^*(x) V(x) \psi_n(x) dx = E_m \int_{-\infty}^{\infty} \psi_m^* \psi_n dx \quad (2)$$

$$0 = (E_n - E_m) \int_{-\infty}^{\infty} \psi_m^* \psi_n dx$$

$$\text{If } E_m \neq E_n \Rightarrow E_n - E_m \neq 0 \Rightarrow \int_{-\infty}^{\infty} \psi_m^* \psi_n dx = 0$$

So, I have got these 2 equations let me remember them number 1 is this one, that I wrote on top and number 2 is this equation. So, I have \hbar^2 cross square over $2m$ integration minus infinity to infinity $d\psi_m^* dx d\psi_n/dx$ integrated plus integration minus infinity to infinity $\psi_m^* x v x \psi_n x$ equals E_n integration minus infinity to infinity $\psi_m^* x \psi_n x dx$ this is my equation number 1. And equation number 2 is \hbar^2 crosses square over $2m$ integration minus infinity to infinity $d\psi_m^* over dx d\psi_n over dx$ integrated over x , plus minus infinity to infinity $\psi_m^* x v x \psi_n x dx$ is equal to E_m integration minus infinity to infinity $\psi_m^* there should be star on top also there is dx \psi_n dx$. This is my equation number 2. Subtract 2 from 1 and when you subtract you notice that the first one cancels. So, does the second term. So, what you are left with is 0 on the left hand side is equal to $E_n - E_m$ integration minus infinity to infinity $\psi_m^* \psi_n dx$.

And now, you can write if E_m is not equal to E_n which implies $E_n - E_m$ is not equal to 0 it immediately means that integration minus infinity to infinity $\psi_m^* \psi_n dx$ is equal to 0. Therefore, you prove the first property of orthogonality of the wave functions, that is one thing we will require later and this is always going to be true in the case of Schrodinger's equation because we require nothing just the solutions of the

Schrodinger equation. The Eigenigen functions whose Eigen values are different, they are orthogonal.

(Refer Slide Time: 15:19)

(II) Normality :

$$\int \psi_m^* \psi_n dx = 0 \quad \text{for } E_m \neq E_n$$

Enforce $\int |\psi_n(x)|^2 dx = 1$

Suppose $\int |\psi_n(x)|^2 dx = C$

$$\psi_n(x) = \frac{\psi_n^{\text{old}}(x)}{\sqrt{C}}$$

$$\int |\psi_n(x)|^2 dx = 1$$

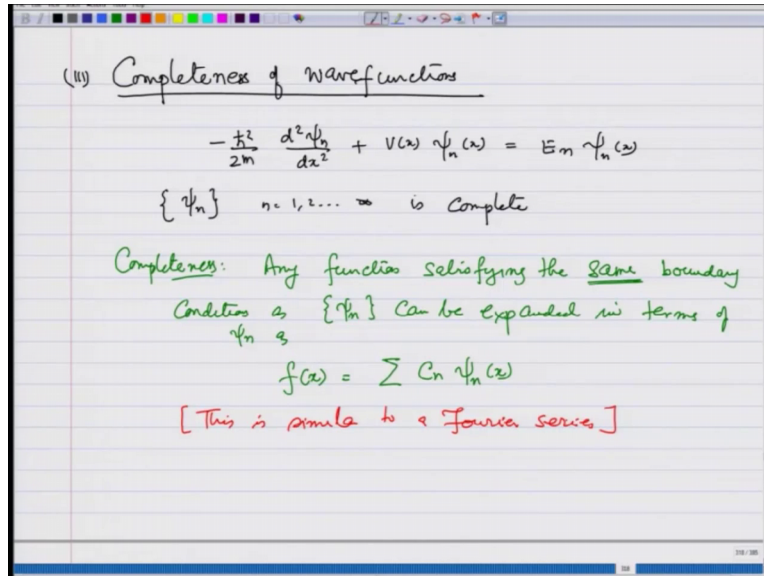

$$\int \psi_m^*(x) \psi_n(x) dx = \delta_{mn} \quad \left[\begin{array}{l} \delta_{mn} = 0 \text{ if } m \neq n \\ \delta_{mn} = 1 \text{ if } m = n \end{array} \right]$$

Number 2 this is the property we are going to enforce is normality. And this will have significance later when I will discuss on interpretation normality is going to be. So, we already seen that $\psi_m^* \psi_n dx$ is 0 for E_m not equal to E_n . And we are going to enforce that integration for the same index mode square dx be equal to 1.

Suppose it is not one suppose. So, let us write suppose integration $\psi_n^2 dx$ is equal to some number c . That I can always defined a new $\psi_n x$ which is equal to the old let me write this old $\psi_n x$ divided by square root of c , So that this condition of normality is going to be enforced because I can always multiply solution of differential equation by constant. So, I can redefine its. So, normality is enforce therefore, in general I am going to write that $\psi_m^* x \psi_n x dx$ is equal to δ_{mn} where δ_{mn} is the prone gal delta. So, on the side I will just write that δ_{mn} is equal to 0, if m is not equal to n and is equal to 1 if m equals n .

So, we have one discuss the property orthogonality, number 2 a convention that going to enforce normality on the wave functions, and third which I will require again is completeness of wave functions.

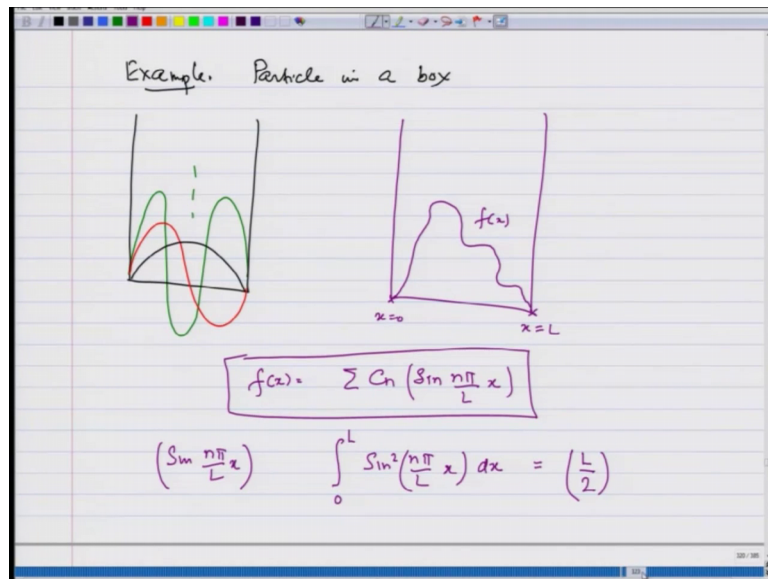

(Refer Slide Time: 17:08)

This is the third property, and that is when I write the Schrodinger's equation minus \hbar^2 cross square over $2m$ $d^2 \psi_n$ over dx^2 plus $V(x) \psi_n(x)$ equals $E_n \psi_n(x)$ then the set ψ_n where n runs from $1, 2$ all the way up to infinity is complete. I am not proving it. So, you can say assuming it, what it means is that any completeness any function general function satisfying the same and that is emphasize same boundary conditions as the set ψ_n can be expanded in terms of ψ_n as $f(x)$ equals summation $C_n \psi_n(x)$. And if you recall from your mathematics this is similar to a Fourier series, where we assume and may be you heard this term earlier that the sin function cosine function and exponential function they form a complete set for those periodic functions.

So here, there are the boundary conditions for the periodicity here the boundary condition satisfied is that satisfied by ψ_n .

(Refer Slide Time: 19:27)

For example so, let us take an example would be let us say particle in a box. So, in the particle in a box if you recall wave function is this function second one is like this, third one is like this and so on. And we assume that this forms a complete set and therefore, any function some arbitrary function which vanishes at the boundaries x equals 0 and x equals L , this is sum $f(x)$ can be written as $f(x)$ equals integration C_n we call these wave functions these functions are $\frac{n\pi}{L} x$, because this satisfies the boundary condition and the C_n can be determined. So, this means that this forms a complete set.

Now, it is as I said convention is to normalize the wave functions. So, the $\sin n x$ is not normalized, because let us see what is the integration. If I integrate from 0 to L $\sin^2 \frac{n\pi}{L} x dx$ this comes out to be L by 2 .

(Refer Slide Time: 21:06)

Normalized particle in a box wavefunction

$$\frac{\sin \frac{n\pi}{L} x}{\sqrt{\frac{L}{2}}} = \sqrt{\frac{2}{L}} \sin \frac{n\pi}{L} x$$

$$\frac{2}{L} \int \sin \left(\frac{m\pi}{L} x \right) \cdot \sin \left(\frac{n\pi}{L} x \right) dx = \delta_{mn}$$

Completeness $f(x) = \sum C_n \phi_n(x)$ $\phi_n = \sqrt{\frac{2}{L}} \sin \frac{n\pi}{L} x$

$$\int_{-\infty}^{\infty} f(x) \phi_m^*(x) dx = \sum_n C_n \int_{-\infty}^{\infty} \phi_m^*(x) \phi_n(x) dx$$

$$= \sum_n C_n \delta_{mn} = C_m$$

$$f(x) = \sum C_n \phi_n(x) \text{ where } C_n = \int f(x) \phi_n^*(x) dx$$

And therefore, to normalize it, I have to write. So, normalized particle in a box wave function would be $\sin n \pi$ over $L x$ divided by square root of L by 2 which is square root of 2 over $L \sin n \pi$ over $L x$. And what an ortho normality is that integration 2 by $L \sin m \pi$ over $L x \sin$ of $n \pi$ over $L x dx$ is equal to δ_{mn} . So, that when m equals n it is one. And when m is not equal to n it is 0 , which you can check yourself. And the claim is for completeness that affects that satisfies the same boundary condition can be written as C_n time is normalized wave function, let me write this as $\phi_n x$ where ϕ_n equal to square root of 2 by $L \sin n \pi$ over $L x$.

How do we determine C_n ? I will multiply $f x$ by $\phi_m^* x dx$ integrate from minus infinity to infinity, which in this case becomes 0 to L which is equal to summation $n C_n \phi_m^* x \phi_n x dx$ minus infinity to infinity, and by ortho normality this becomes summation over $n C_n \delta_{mn}$ and this equals c_m . So, we have also determined c_m ; that means, $f x$ is equal to summation $C_n \phi_n x$ where C_n is nothing but integration of $f x \phi_n^* x dx$, that is completeness needs.

Now, I am going to write completeness in a different form and that is useful later, writing completeness in terms of dirac delta function.

(Refer Slide Time: 23:35)

Writing Completeness in terms of Dirac-Delta function.

$$f(x) = \sum_n C_n \varphi_n(x)$$

$$C_n = \int_{-\infty}^{\infty} f(x') \varphi_n^*(x') dx'$$

$$f(x) = \sum_n \left(\int_{-\infty}^{\infty} f(x') \varphi_n^*(x') dx' \right) \varphi_n(x)$$

$$= \int_{-\infty}^{\infty} dx' f(x') \left[\sum_n \varphi_n^*(x') \varphi_n(x) \right]$$

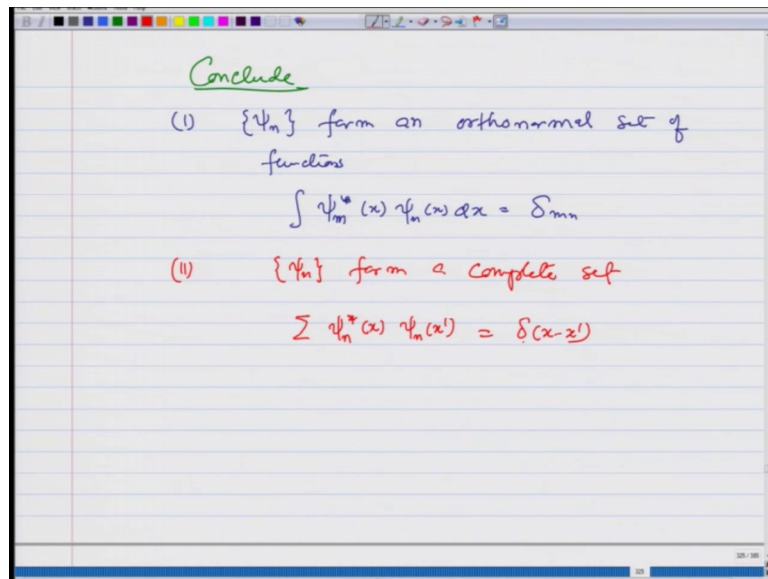

$$f(x) = \int_{-\infty}^{\infty} dx' f(x') \delta(x-x')$$

$$\sum_n \varphi_n^*(x') \varphi_n(x) = \sum_n \varphi_n^*(x') \varphi_n(x) = \delta(x-x')$$

So, what we have just said is that $f(x)$ is equal to summation $\sum_n C_n \varphi_n(x)$ where C_n is equal to integration minus infinity to infinity, $f(x')$ and let me write this $f(x') \varphi_n^*(x')$ dx' . Because x' is a dummy variable x I am using earliest. So, I do not want to use that again and then I have $f(x)$ is equal to summation over n integration minus infinity to infinity $f(x') \varphi_n^*(x')$ $\varphi_n(x)$. I can rearrange terms and write this as integration minus infinity to infinity $dx' f(x')$ and then take the sum inside because that acts only on φ_n^* and φ_n $\sum_n \varphi_n^*(x') \varphi_n(x)$. This is what completeness is given us.

Now, I also know that $f(x)$ is equal to minus infinity to infinity, and $dx' f(x') \delta(x-x')$. And this immediately tells me these 2 things together tell me that the summation $\sum_n \varphi_n^*(x') \varphi_n(x)$ is equal to $\delta(x-x')$. Which I also can write as switch the indices summation $\sum_n \varphi_n^*(x) \varphi_n(x')$ and the same thing because delta function it does not matter if I change x and x' indices. So, this is another way of expressing completeness.

(Refer Slide Time: 26:17)

So, let me conclude this lecture with introduction to mathematics by writing number 1, ψ_n form a an ortho normal set of functions. And what that means, is integration $\psi_m^* \psi_n dx$ is equal to δ_{mn} . And the other property that ψ_n normalized form a complete set and that means, summation $\psi_n^* \psi_n(x')$ is equal to $\delta(x-x')$.

In the next lecture I will use these properties to show the equivalence of Heisenberg's and Schroedinger's approaches to quantum mechanics.
