Lecture – 05

Black Body Radiation V- Wein's displacement law and analysis for spectral density

In this lecture we are going to derive Wien's formulas.

(Refer Slide Time: 00:17)

In particular we are going to look at Wien's displacement law and Wien's distribution and both are done using thermodynamics and as you must know, the thermodynamic does not really care about the details of interaction. It is a macroscopic theory and let us look at these beautiful arguments by Wien and he came very very close to obtaining the true formula for the distribution of spectral density and he was actually awarded Nobel Prize for this discovery.

So, first thing is Wien's displacement law, for this he considered a spherical cavity which; let us say this expanding or contracting by a very slow; very small velocity v , it could be either way by small velocity V and so he considered adiabatic expansion of a cavity which is spherical cavity (Refer Time: 01:59) adiabatic expansion of a spherical cavity; adiabatic means that will tuck you heat exchange was 0 at temperature T .

What we have seen earlier is that if I have a cavity like this, right, it applying a pressure which is applying pressure p , when it is allowed to expand adiabatically keeping it in equilibrium, right. So, I will be applying some force on it and therefore, it does work. So, the cavity or more appropriately radiation inside, the cavity does work as the cavity expands. So, as the cavity expands, it does work, if it does work, what should happen to its internal energy? This implies internal energy u becomes a smaller because the work is done at the cost of this energy because there is no heat being supplied and this implies the temperature goes down volume is increasing, temperature is going down.

At the same time, if I were to compress it if the radius was going down the temperature would go up because I will be pumping in energy something more happens as the radiation inside bounces around the cavity as it expands. So, you recall from a twelfth grade physics if a light or sound reflects from a moving wall its wavelength changes its frequency changes.

So, any light at λ as it bounces s λ is going to increase because frequency is going to go down. So, I can actually by studying this adiabatic expansion I can relate how much is the changes is λ and how is that λ related to T and that is what we ended and we are going to do it next.

(Refer Slide Time: 04:34)

The whiteboard contains two diagrams of a spherical cavity of radius r . The top diagram shows a light ray reflecting off the inner surface at an angle θ from the normal, with the angle between the incident and reflected rays labeled as $\pi - 2\theta$. The bottom diagram shows a similar setup but with a velocity vector u pointing outwards from the center, and the angle of reflection labeled as $\theta + \alpha$.

Change in the wavelength is given by
 Doppler formula ($v \ll c$)

$$\frac{\Delta \lambda}{\lambda} = \frac{2v \sin \theta}{c}$$

$$\Delta \lambda = \lambda \left(\frac{2v \sin \theta}{c} \right) \text{ per reflection}$$

Calculation of temperature change
 (Use first law of Thermodynamics)

$$\Delta Q = \Delta U + p \Delta V$$

$$\Delta U = -p \Delta V = -\frac{u}{3} \cdot 4\pi r^2 \Delta r$$

$$\Delta U = \Delta(uV) = \Delta u V + u \Delta V$$

$$= \Delta u V + u \cdot 4\pi r^2 \Delta r$$

$$\Delta u \frac{4\pi r^3}{3} + u \cdot 4\pi r^2 \Delta r = -\frac{u}{3} \cdot 4\pi r^2 \Delta r$$

$$\Delta u \frac{r}{3} = -\frac{4u}{3} \Delta r$$

So, let us see now; how these changes occur when this cavity has radius r and light ray is going such that from the centre, if I draw a perpendicular to this the angle where it hits is

theta and this slightly reflects again and this is going to be pi by 2 minus theta and so, is the (Refer Time: 05:00) let me make it here again cleanly. So, there is the light ray which is going this is a centre, this angle is theta, the light ray gets reflected like this and the cavity is expanding in this direction with velocity V.

Now change in the wavelength is given by Doppler's formula and V is much much less than c. So, $\frac{\Delta \lambda}{\lambda}$ is given as $\frac{2V \sin \theta}{c}$ the component of V is going to be taken in the direction of light which is V sine theta. So, this is going to be $\frac{2V \sin \theta}{c}$ divided by c. So, this is going to be $\Delta \lambda$ is equal to $\lambda \frac{2V \sin \theta}{c}$ over c per reflection.

So, during each reflection this is the change in the wavelength and I want to relate this to the temperature change; how do we calculate the temperature change? So, the calculations of temperature change. This is done using first law of thermodynamics which says that Δq is equal to $\Delta u + p \Delta V$. Now I am taking an adiabatic expansion. So, this is 0. and therefore Δu is going to be equal to $-p \Delta V$ which I can write as $-u \frac{4\pi r^2 \Delta r}{3}$ where r is the radius of the cavity Δu is nothing, but Δu times V which is going to be $\Delta u V$ plus $u \Delta V$ which is $\Delta u V$ plus $u \frac{4\pi r^2 \Delta r}{3}$. So, let us collect this all together on the left hand side, we have $\Delta u V$ is $\frac{4\pi r^3}{3} + u \frac{4\pi r^2 \Delta r}{3}$ is equal to $-u \frac{4\pi r^2 \Delta r}{3}$.

Now, I can write this $\frac{4\pi r^2}{3}$ cancels from all through $\frac{4\pi r^2}{3} + u \frac{4\pi r^2 \Delta r}{3}$ $\frac{4\pi r^2}{3}$ $\frac{4\pi r^2}{3}$ $\frac{4\pi r^2}{3}$ r square. So, you get $\Delta u r \pi^3$ is equal to $-4u \frac{\Delta r}{3}$. So, this is a result which we have got which I will through take to the next slide.

(Refer Slide Time: 08:48)

$$\frac{\Delta u}{r} = -4 \frac{\Delta r}{u}$$

$$\left(\frac{\Delta u}{u} = -4 \frac{\Delta r}{r} \right)$$

$$u \propto T^4 \Rightarrow \Delta u \propto 4 T^3 \Delta T$$

$$\frac{\Delta u}{u} = \frac{4 T^3 \Delta T}{T^4} = \frac{4 \Delta T}{T}$$

$$\cancel{4} \frac{\Delta T}{T} = -\cancel{4} \frac{\Delta r}{r} \quad \frac{\Delta T}{T} = -\frac{\Delta r}{r}$$

$$\frac{dT}{T} = -\frac{dr}{r} \Rightarrow (Tr) = \text{Constant}$$

we have related T and radius
we have found $\Delta \lambda = \lambda \left(\frac{2v \sin \theta}{c} \right)$ per reflection

So, we have got $\Delta u / r$ by 3 is equal to minus 4 $\Delta r / u$ by 3; this 3 cancels and I get $\Delta u / u$ equals minus 4 $\Delta r / r$. Now I know that u is proportional to T raised to 4 which implies Δu is proportional to 4 T raised to 3 ΔT , if I substitute that I am going to get $\Delta u / u$ is equal to 4 T cube ΔT over T raised to 4 which is 4 ΔT over T . So, from this combining all this, I get 4 ΔT over T is equal to minus 4 Δr over r this 4 cancels and I get ΔT over T is equal to minus Δr over r $d T$ over T is equal to minus $d r$ over r implies immediately that T times r is equal to a constant.

(Refer Slide Time: 10:56)

$$\frac{\Delta \lambda}{\lambda} = \frac{2v \sin \theta}{c} \text{ per reflection}$$

time per reflection is $\frac{2r \sin \theta}{c}$

Distance travelled by the cavity walls in this time = $\Delta r = \left(\frac{2r \sin \theta}{c} \right) v$

$$= \left(\frac{2v \sin \theta}{c} \right) r$$

$$\Rightarrow \frac{2v \sin \theta}{c} = \left(\frac{\Delta r}{r} \right)$$

$$\frac{\Delta \lambda}{\lambda} = \frac{\Delta r}{r} \text{ or } \frac{d\lambda}{\lambda} = \frac{dr}{r}$$

$$\Rightarrow \left(\frac{\lambda}{r} \right) = \text{Constant}$$

$\lambda = cr$
 $\frac{d\lambda}{\lambda} = \frac{cdr}{cr} = \frac{dr}{r}$

As the radius goes up, the temperature comes down. So, we have related temperature and radius and we have also found $\Delta \lambda$ is equal to $\lambda \frac{2V \sin \theta}{c}$ per reflection and we combine these 2 to relate λ and T let us see how we do that $\Delta \lambda$ over λ is $\frac{2V \sin \theta}{c}$ per reflection. Now per each reflection the distance travelled by light is if the radius is r then time per reflection is $\frac{2r \sin \theta}{c}$ because this is r this is θ . So, this is $r \sin \theta$ this is $r \sin \theta$. So, $2r \sin \theta$ divided by c time per reflection is $\frac{2r \sin \theta}{c}$.

So, the distance travelled by the cavity walls in this time is going to be equal to Δr which is equal to $\frac{2r \sin \theta}{c} \times V$ which is I can write as $\frac{2V \sin \theta}{c}$ times r . This implies to $\frac{V \sin \theta}{c}$ can be written as $\frac{\Delta r}{r}$. Now I substitute this in this formula and get $\Delta \lambda$ over λ is equal to $\frac{\Delta r}{r}$ or $d\lambda$ over λ equals $d r$ over r and this immediately gives you that λ over r is a constant.

Let us check that λ equals c times r $d\lambda$ is equal to $c d r$ $d\lambda$ over λ is equal to $c d r$ over $c r$ which is $d r$ over r . So, this checks λ over r is a constant.

(Refer Slide Time: 13:36)

$(Tr) = \text{Constant} = C_1 \quad \text{--- (I)}$
 $\left(\frac{\lambda}{r}\right) = \text{Constant} = C_2 \quad \text{--- (II)}$
 $(T\lambda) = \text{Constant}$
 $T_1 \lambda_1 = T_2 \lambda_2$
Feature chosen to identify λ'
 λ_{max}
 $\lambda_{\text{max}} T = \text{Constant}$
 $\lambda_{\text{max}} T \approx 2900 \mu\text{m} \cdot \text{K}$

So, what have we got? We have got T times r is a constant, let us call this c_1 and we have also got just now that λ over r is a constant which is some c_2 , we can combine the 2 and multiply both equations; this equation 1 and this equation 2. This tells

me that T times λ is equal to some constant; what does this mean? This means in this cavity as it expands, the radiation remains at equilibrium. It goes from T_1 to T_2 , if I look at a particular wavelength and keep following it, this λ changes from λ_1 to λ_2 ; it will be such that $T_1 \lambda_1 = T_2 \lambda_2$.

This λ has to correspond to certain feature of the radiation. So, the feature we choose; feature chosen to identify λ is λ_{max} and then we write $\lambda_{\text{max}} T$ is equal to constant and this was confirmed by experiments carried out and they found that $\lambda_{\text{max}} T$ is of the order of 2900 micrometer k. So, this is confirmed and therefore, Wien's analysis was correct, this analysis was also used for the first time to estimate the temperature of distant stars, and things like those because you have to find in their spectrum where λ_{max} is and put that in this formula and find the temperature of that now that star.

(Refer Slide Time: 15:33)

The second one is more important and for this what Wien considered is that when form a high temperature T_1 , if I go to a lower temperature T_2 radiation which was contained between say λ and $\lambda + \Delta \lambda$ when T_2 radiation is shifted because of that displacement formula, some λ' ; $\lambda' + \Delta \lambda'$ the energy content. In the first case, T_1 was $u_{\lambda} \Delta \lambda$ and this became energy content.

In the second case which is $u_{\lambda'} \Delta \lambda'$ and I should be careful this is at temperature T_2 . So, what we have is that $u_{\lambda} \Delta \lambda$ went to $u_{\lambda'} \Delta \lambda'$ at T_2 . However, I know what the temperature dependence is the energy content is proportional to T raised to 4, mind you, I am not going to take a ratio of energy density, but energy content. And therefore, I am going to have $u_{\lambda} \Delta \lambda$ over T_1 raised to 4 is equal to $u_{\lambda'} \Delta \lambda'$ over T_2 raised to 4.

That should be the ratio by a Stefan Boltzmann law; what we are assuming is the Stefan Boltzmann law holds even for energy content in small intervals, all right, but you know you get your answer and if they match you are on the right track. So now you have therefore, that this relationship. Now notice that λT_1 is equal to $\lambda' T_2$ and this immediately gives you; this together gives you $\Delta \lambda T_1$ is equal to $\Delta \lambda' T_2$ and we will substitute this in this equation and I am going to get $u_{\lambda} \Delta \lambda$ is going to be proportional to $1/T_1$ over T_1 raised to 5 is going to be equal to $u_{\lambda'} \Delta \lambda'$ over T_2 raised to 5.

(Refer Slide Time: 18:56)

Handwritten derivation on a whiteboard:

$$\lambda T = \text{Constant}$$

$$u_{\lambda}(T) \lambda^5 = \text{Constant}$$

$$\lambda' = \frac{\lambda T}{T'}$$

$$u_{\lambda}(T) \lambda^5 = u_{\lambda'}(T') \lambda'^5$$

$$u_{\lambda}(T) \lambda^5 = u_{\lambda'}(T') \left(\frac{\lambda T}{T'}\right)^5$$

$$u_{\lambda}(T) \lambda^5 = u_{\lambda'}(T') \lambda^5 \frac{T^5}{T'^5}$$

$$u_{\lambda}(T) = u_{\lambda'}(T') \frac{T^5}{T'^5}$$

$$u_{\lambda}(T) = \frac{f(\lambda T)}{\lambda^5}$$

$$u_{\lambda} \Delta \lambda = u_{\nu} \Delta \nu$$

$$u_{\lambda} = \frac{c^2}{\lambda^5} u_{\nu}$$

$$\frac{\nu^5 f(\lambda T)}{c^5} = \frac{\nu^2}{c} u_{\nu}(T)$$

$$\Rightarrow u_{\nu}(T) = z(\nu/T) \nu^3$$

So, through the analysis of this curve and the way λ shifts, we have found that $u_{\lambda} \Delta \lambda$ over T raised to 5 is same as $u_{\lambda'} \Delta \lambda'$ over T' raised to 5. Now, I also know that λT remains constant. So, this

implies that $u(\lambda, T)$ over that constant raised to 5; λ raised to 5 is equal to $u(\lambda', T')$ λ' raised to 5 and this is a constant, right. So, what we have got through this analysis that $u(\lambda, T) \lambda^5$ is equal to $u(\lambda', T')$ λ'^5 is a constant. What kind of constant is going to be I know; obviously, that $u(\lambda, T)$ depends both on λ and temperature.

So, this constant; I am going to write as some function f of λ, T because λ, T does not change as you go from one place to the other and therefore, as you increase this cavity size or if you change the temperature from one black body radiation to the other. So, this is going to be a function of λ, T in most general form, otherwise it would have been a constant throughout, but that would not give you u as a function of λ and T both. And therefore, we put this and this immediately tells you that $u(\lambda, T)$ is of the form some function of λ, T divided by λ^5 .

This is Wien's distribution, this also tells you that since $u(\lambda, \Delta\lambda)$ be equated to $u(\nu, \Delta\nu)$ and if you recall from my previous lecture, one of the previous lectures, we have obtained that $u(\lambda)$ was ν^2 over c $u(\nu)$. So, $u(\lambda)$ is $f(\lambda, T)$ over λ^5 which can be written as $c^5 \nu^5$ is equal to ν^2 over c $u(\nu, T)$ and this implies $u(\nu, T)$ is of the form some other function $g(\nu)$ over T , I have written λ as c over λ which is T over ν which can also write as ν over T times ν^3 .

So, these are 2 forms that have been derived by Wien that were derived by Wien, important thing that I am going to write on the side is our; what we have obtained is λ, T is a constant and $u(\lambda, T) \lambda^5$ is a constant for each given λ . So, if I am given the experimental curve as a particular temperature for different λ 's, I can always find the curve at some other temperature because as the temperature changes, I will find the corresponding λ' which will be equal to λ, T over T' and then using this formula which says that $u(\lambda, T) \lambda^5$ is equal to $u(\lambda', T')$ λ'^5 , I can find $u(\lambda', T')$.

So, given experimental curve at one particular temperature, the experimental curve for spectral density, I can find these spectral density at any other temperature that is the

utility of Wien's formula, we will analyze it further vis-a-vis, we experimental curves in the next few lectures.
