Lecture - 08
Radiation as a collection of particles called photons

In the previous lecture, what we have seen is that the quantum hypothesis.

(Refer Slide Time: 00:21)

That is an oscillator can take energies $0, h\nu, 2h\nu$ and so on explains the black body spectral density. So, this is only the oscillator. So, what we had assumed that there is a cavity and these oscillators take only quantized value, but at the same time, with treating the radiation as if it is continuous, this seems to be an inconsistency. And that is where Einstein came in and he said maybe radiation should also be treated as this continuous containing particles of energy $h\nu$ and he went on to show this I want to do it for you, because this is a beautiful piece of scientific investigation.

So, why; what Einstein says is that for a system where Wien's formula for radiation is valid and that is a regime where ν/T is large, when this is valid, the radiation behaves like a collection of particles each with energy $h\nu$ and that gives the concept of photon and we want to see; how it did; that use a little bit of thermodynamics, right. So, thermodynamics says that $1/T$ is equal to dS/dU at constant volume.

Now, what Einstein considers is that S is also made up of a spectral s_{ν} and U is given by U_{ν} and without proof, I am now going to claim that $1/T$ is also equal to ds_{ν}/dU_{ν} at constant volume. So, even the partial whatever the spectral density of the entropy is one of the internal energy is there partial derivative gives you $1/T$.

(Refer Slide Time: 03:53)

The whiteboard contains the following handwritten mathematical derivation:

$$\frac{1}{T} = \frac{\partial s(\nu)}{\partial u(\nu)}$$

From Wien's formula

$$u(\nu) = \alpha \nu^3 e^{-\beta \nu / kT}$$

$$\frac{u(\nu)}{\alpha \nu^3} = e^{-\beta \nu / kT}$$

$$\ln \left(\frac{u(\nu)}{\alpha \nu^3} \right) = -\frac{\beta \nu}{kT}$$

$$\therefore \frac{1}{T} = -\frac{k}{\beta \nu} \ln \left(\frac{u(\nu)}{\alpha \nu^3} \right)$$

$$= -\frac{k}{\beta \nu} \ln \left(\frac{u}{\alpha \nu^3} \right) = \frac{\partial s(\nu)}{\partial u(\nu)}$$

$$s(\nu) = \int -\frac{k}{\beta \nu} [\ln u - \ln(\alpha \nu^3)] d u$$

$$= -\frac{k}{\beta \nu} [u \ln u - u - u \ln \alpha \nu^3]$$

So, what we have is $1/T$ equals ds_{ν}/dU_{ν} . Now from Wien's formula, we have u_{ν} is equal to $\sum \alpha e^{-\beta \nu / kT}$ and there is a ν cubed. So, u_{ν} over $\alpha \nu$ cubed is equal to $e^{-\beta \nu / kT}$. Take log of both sides and you get $\ln(u_{\nu} / \alpha \nu^3)$ is equal to $-\beta \nu / kT$ or $1/T$ is equal to $k / \beta \nu \ln(u_{\nu} / \alpha \nu^3)$.

And therefore, I have $1/T$ which is $-\frac{k}{\beta \nu} \ln(u / \alpha \nu^3)$ equals ds_{ν}/dU_{ν} , we integrate this and we get s_{ν} ; small s_{ν} is equal to $\int -\frac{k}{\beta \nu} [\ln u - \ln(\alpha \nu^3)] d u$ which is $-\frac{k}{\beta \nu} [u \ln u - u - u \ln \alpha \nu^3]$ let me simplify this.

(Refer Slide Time: 06:08)

The image shows a handwritten derivation on a whiteboard. At the top, the entropy density $s(\nu)$ is given as $-\frac{k}{\beta\nu} [u \ln u - u - u \ln(\alpha\nu^3)]$. This is simplified to $-\frac{k}{\beta\nu} [\ln(\frac{u}{\alpha\nu^3}) - 1]$. Then, the total entropy S is calculated as $S = \int V \cdot s(\nu) d\nu = -\frac{k}{\beta\nu} \int u d\nu [\ln(\frac{u}{\alpha\nu^3}) - 1]$. A small diagram shows a vertical double-headed arrow labeled ν and a horizontal double-headed arrow labeled $d\nu$. Below this, the energy E is defined as $E = \int u d\nu$. The final boxed equation is $S = -\frac{kE}{\beta\nu} \ln(\frac{E}{\alpha V \nu^3 d\nu}) - 1$. At the bottom, there are two lines of text: "Entropy of radiation between frequency ν & $\nu + d\nu$ " and "Change the volume from V_1 to V_2 keep E unchanged".

So, let me see; what we got. We have got s equals minus k over $\beta\nu$ times $u \ln u - u - u \ln(\alpha\nu^3)$ inside, I get $u \log$ of u minus u minus $u \log$ of $\alpha\nu^3$ which I can write as minus k over $\beta\nu$ times u , I can take out \log of u over $\alpha\nu^3$ minus 1. This is s , this is the entropy density.

So, now I consider in this cavity a small interval of $d\nu$. So, the entropy of the entire cavity is going to be volume times s times $d\nu$ which I can write as minus k times u times V over $\beta\nu$ times \log of u over $\alpha\nu^3$ minus 1. Now notice that u times V is the energy contained between u and $u + d\nu$. So, S is equal to minus k times the energy over $\beta\nu$ times \log of I can write this as u times V again. So, energy over α volume ν^3 times $d\nu$ minus one this is the entropy of radiation. So, I can write this entropy of radiation between frequency ν and $\nu + d\nu$, in volume V . Now consider change the volume from V_1 to V_2 keeping E unchanged keeping the energy of the system unchanged.

(Refer Slide Time: 08:47)

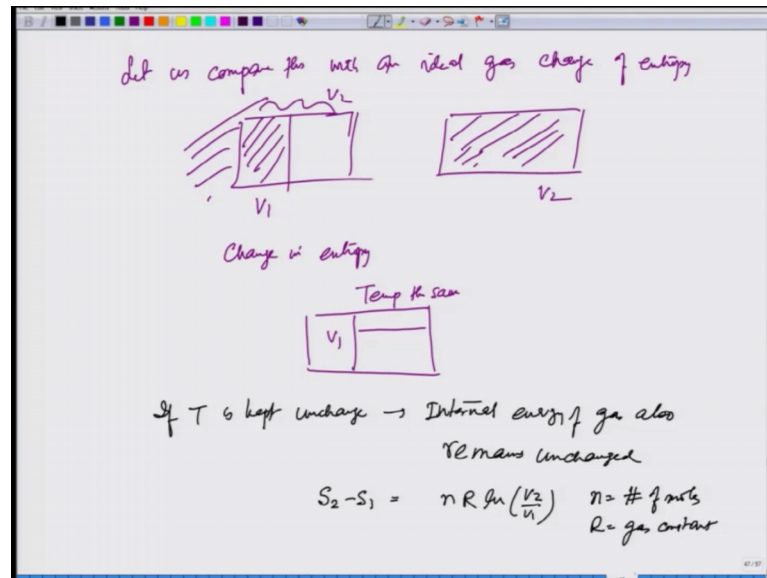

$$S_1 = -\frac{kE}{\beta\nu} \left[\ln \left(\frac{E}{V_1 \alpha \nu^3 d\nu} \right) - 1 \right]$$
$$S_2 = -\frac{kE}{\beta\nu} \left[\ln \left(\frac{E}{V_2 \alpha \nu^3 d\nu} \right) - 1 \right]$$
$$= \frac{kE}{\beta\nu} \left[-\ln \left(\frac{E}{V_2 \alpha \nu^3 d\nu} \right) + \ln \left(\frac{E}{V_1 \alpha \nu^3 d\nu} \right) \right]$$
$$S_2 - S_1 = \frac{kE}{\beta\nu} \ln \left(\frac{V_2}{V_1} \right)$$

Change in the entropy of radiation when E is kept constant and volume is changed from V_1 to V_2
Under the condition that $\nu/T \rightarrow \text{large}$

Then you are going to get. So, S_1 is going to be minus $k e$ over $\beta \nu$ \log of E over $V_1 \alpha \nu^3 d \nu$ minus one this is V_1 , S_2 is going to be minus $k E$ over $\beta \nu$ \log of E is remaining unchanged, $V_2 \alpha \nu^3 d \nu$ minus one is going to be $k E$ over $\beta \nu$ \log of E over V_2 minus \log of E over $V_2 \alpha \nu^3 d \nu$ plus \log of E over $V_1 \alpha \nu^3 d \nu$.

So, this gives $S_2 - S_1$ is equal to $k E$ over $\beta \nu$ \log of V_2 over V_1 . So, this is the change in the entropy of radiation when E is kept constant and volume is changed from V_1 to V_2 and this is also under the condition that ν over T is large. So, T is small.

(Refer Slide Time: 10:51)

Now, let us compare this with an ideal gas change of entropy, if I take an ideal gas fill 1 half or 1 portion of a container which is isolated from surroundings right of V_1 and this whole volume is V_2 and puncture this wall.

When I puncture this wall, what happens is the entire container gets filled and there is a change in entropy and this change in entropy can we calculate very easily what we do is push this gas back to volume V_1 keeping the temperature the same. If the temperature is kept the same if T is kept unchanged the internal energy of gas also remains unchanged and I leave it as an exercise for you to show that; in this case, if we calculate the entropy change you get $S_2 - S_1$ to be equal to $nR \ln \frac{V_2}{V_1}$ where n is the number of mols and R is gas constant.

(Refer Slide Time: 13:02)

In case of radiation

$$S_2 - S_1 = \frac{kE}{\beta\nu} \ln\left(\frac{V_2}{V_1}\right) = \frac{kE}{h\nu} \ln\left(\frac{V_2}{V_1}\right)$$
$$= \frac{R}{N} \left(\frac{E}{h\nu}\right) \ln\left(\frac{V_2}{V_1}\right)$$

Ideal gas

$$S_2 - S_1 = nR \ln\left(\frac{V_2}{V_1}\right)$$

We can consider the radiation as having # of mols

$$= \frac{1}{N} \left(\frac{E}{h\nu}\right) \text{ and behaving like an ideal gas}$$

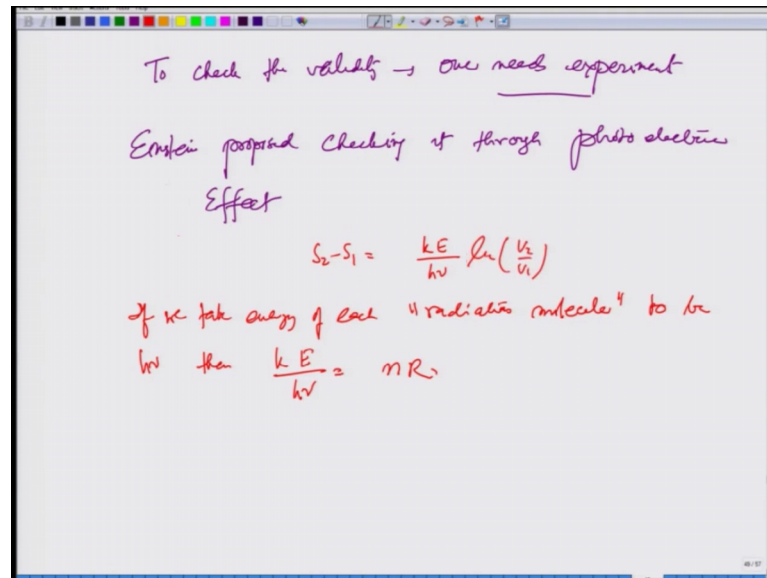

$\Rightarrow \frac{E}{h\nu} = \text{number of "radiation gas" particles}$

$$\frac{1}{N} \left(\frac{E}{h\nu}\right) = \# \text{ of mols}$$

So, what we have learnt is that in case of radiation the change in entropy S_2 minus S_1 come out to be kE over $\beta\nu$ \ln of V_2 over V_1 , we know the value of β is $1/h$. So, this is kE over $h\nu$ \ln of V_2 over V_1 which I can write as k is nothing, but R over n , n is the Avogadro number E over $h\nu$ \ln of V_2 over V_1 and in gases S_2 minus S_1 comes out to be nR \ln of V_2 over V_1 .

So, this means, we can consider the radiation as having number of mols equals 1 over nR over $h\nu$, right number of mols equals this much and behaving like an ideal gas. So, this also implies then immediately that E over $h\nu$ is equal to the number of radiation gas particles. So, that $1/n$; n is Avogadro number E over $h\nu$ becomes number of mols.

(Refer Slide Time: 15:35)

So, this analogy between entropy change of the radiation when it is allowed to change volume without change in the energy and ideal gas gives you an idea that it can be treated like collection of molecules, but that is just a showing it theoretical to check the validity one needs experiments. So, for that Einstein proposed checking it through photoelectric effect. So, let me give you again that $S_2 - S_1$ comes out to be $kE/h\nu \ln(V_2/V_1)$ and if we take energy of each radiation molecule to be $h\nu$ then $kE/h\nu$ comes out to be nR .

Just like ideal gas and that is what gives Einstein the idea that I can think of this as a collection of particles with each having energy $h\nu$ and n becomes nE/h $kE/h\nu$ becomes nR and then through photoelectric effect, it is checked and everything comes out to be correct, I am not going to do photoelectric effect here because you studied it many many times in your 12th grade and so on. So, this is what gave the idea of radiation; also having this particle nature of $h\nu$ and experimental evidence was photoelectric effect. He also applied it to some other effects; call them; you know when the radiation goes out, radiation hits an atom and goes out, its frequency changes such that the wavelength increases its frequency goes down. So, it is given part of his energy through the atom.

What we will do next is again apply Einstein ideas; Einstein's to study the low temperature behavior of solids to see that the ideas of quantization of an oscillator can also be applied to mechanical oscillators.
