**Calculating density of states of phonons; the Einstein's and the Debey models**

(Refer Slide Time: 00:17)

$\mathcal{D}(k)$  = density of states in  $k$ -space

One dimensional case

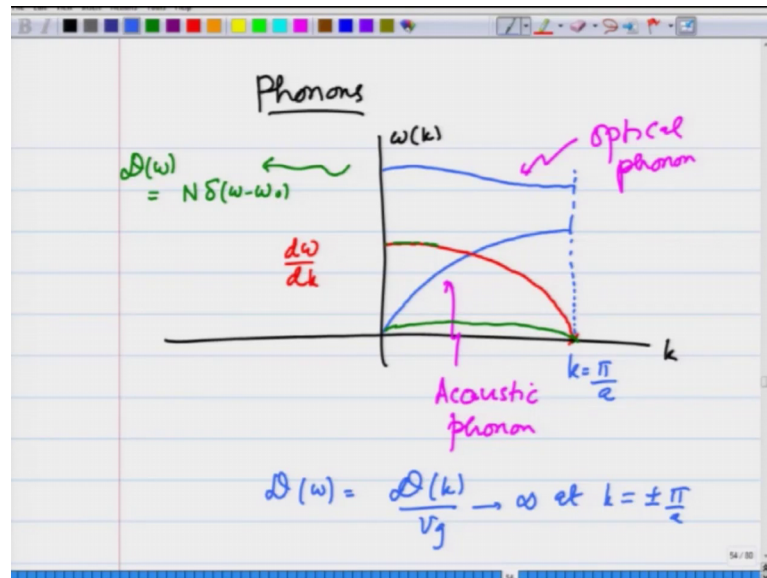

$$\mathcal{D}(\omega) = \frac{\mathcal{D}(k)}{(d\omega/dk)} = \frac{\mathcal{D}(k)}{v_g}$$

$$\mathcal{D}(\omega) = \frac{1}{v_g} \left( \frac{L}{2\pi} \right)$$

$\mathcal{D}(\omega) d\omega$  = Number of modes between  $\omega$  and  $\omega + d\omega$

In the previous lecture, we obtained  $\mathcal{D}(k)$ , which gives the density of states in  $k$  space. And we did it for one-dimensional case. We were also shown there that  $\mathcal{D}(\omega)$  is nothing but  $\mathcal{D}(k)$  divided by  $d\omega/dk$  which is equal to  $\mathcal{D}(k)$  over  $v_g$ . So, having obtained  $\mathcal{D}(k)$ , I can write  $\mathcal{D}(\omega)$  is equal to  $L$  over  $2\pi$   $1$  over  $v_g$  group that is my density of states in  $\omega$  space, so that  $\mathcal{D}(\omega)$  times  $d\omega$  gives number of modes between frequency  $\omega$  and  $\omega + d\omega$ .

(Refer Slide Time: 01:39)

Now, recall that when we discussed phonons, this is all in the context of phonons, we had  $\omega(k)$  versus  $k$  as acoustic phonons here, I am making only on one side the other side is symmetric this is  $k$  over  $k$  equals  $\pi$  over  $a$ . And the other phonon like this, we call this the acoustic phonon, and this one optical phonon. And what you can see let us focus on acoustic phonon that  $d\omega/dk$  if I were to plot for acoustic phonon, and I will plot it right here if I were to plot  $d\omega/dk$ , you will see this is has a finite value and slowly becomes smaller and goes to 0 at  $\pi$  over  $a$ .

In the case of  $\omega(k)$  for the optical phonons also you can see that for the optical phonons it will be almost 0 here and  $d\omega/dk$  goes to very small value and goes to 0 again. In fact, to a good approximation here I can write  $D(\omega)$  as  $N\delta(\omega - \omega_0)$ , I will explain that in a minute.

Here there is some finite value and then  $v_g$  goes to 0 here. Now, you see if I were to calculate the  $\omega$  from  $D(k)$  divided by  $v_g$ , it goes to infinity at  $k$  equals plus minus  $\pi$  by  $a$ , it blows up. I need a model through, which I can work and which is a reasonable model and this is what we are going to do in this lecture.

(Refer Slide Time: 03:59)

$$D(\omega) = \frac{D(k)}{v_g}$$

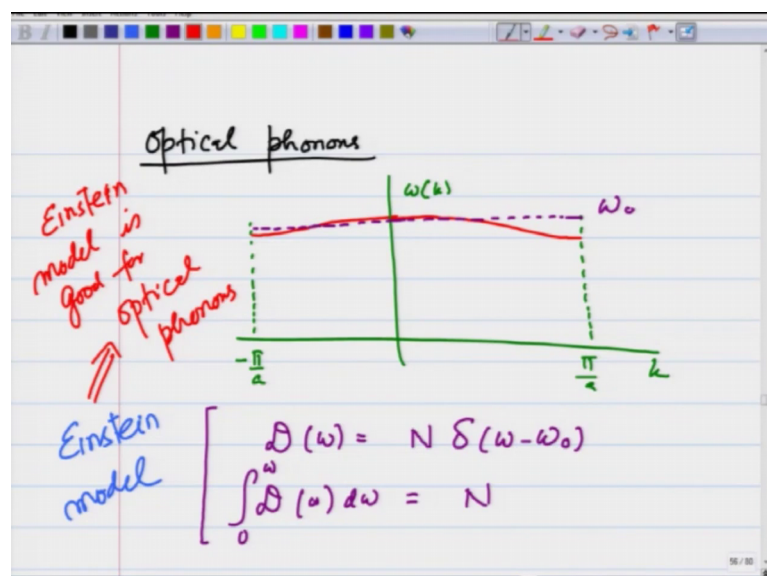

$$D(k) = \left(\frac{L}{2\pi}\right)$$

$$\int_{-\frac{\pi}{a}}^{\frac{\pi}{a}} D(k) dk = \frac{L}{2\pi} \times \frac{2\pi}{a} = \frac{L}{a} = N$$

$$\int_0^{\omega_{\max}} D(\omega) d\omega = N.$$

So, we had derived the omega, which is  $D(k) / v_g$ .  $D(k)$  is equal to  $L / (2\pi)$ . If I integrate the density of states from  $k = -\pi/a$  to  $\pi/a$ , it must lead to the total number of modes which is  $N$ , because this is going to be  $L / (2\pi) \times 2\pi/a$ , which is  $L/a$ , which is equal to  $N$ . Similarly, if I integrate  $D(\omega)$  from  $\omega = 0$  to some  $\omega_{\max}$ , it should give me  $N$ . So, we will be working through these equations, we have understood the meaning of the density of states, we have understood what it integrates to, and through these now we will be doing the calculations for energies and things like those.

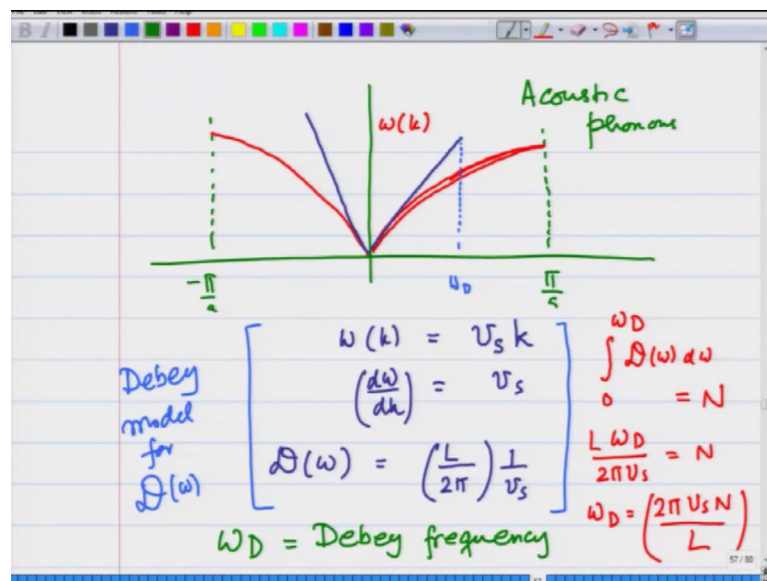

(Refer Slide Time: 05:11)

Now, as I said earlier if I were to look at the optical phonons, what we see is that  $\omega$  versus  $k$  if I were to plot it up to some point  $\pi/a$  by a here, it is almost flat like this same thing on the other side almost flat. And you can see that there is only one  $\omega$  I mean if I approximated this we can say one  $\omega$  some  $\omega_0$  at which all the atoms are vibrating and therefore, I can just by inspection write  $D(\omega)$  as number of modes  $\Delta\omega$  minus  $\omega_0$ .

So, that when I integrate  $D(\omega)$  over this range  $0$  to some  $\omega$  the point including  $\omega_0$  the number of modes come out to be precisely the same as the number of atoms in that chain of length  $L$  which it should be. So, this is a very simple model of density of states and this is known as the Einstein model. There is another model for the density of states which, I will call Debye model which I will explain next, but first the Einstein model this is good right I can see it right away. So, Einstein model let me write it on the left side of the screen, Einstein model it is good for optical phonons, because in optical phonons the, the frequency is almost constant.

(Refer Slide Time: 07:23)

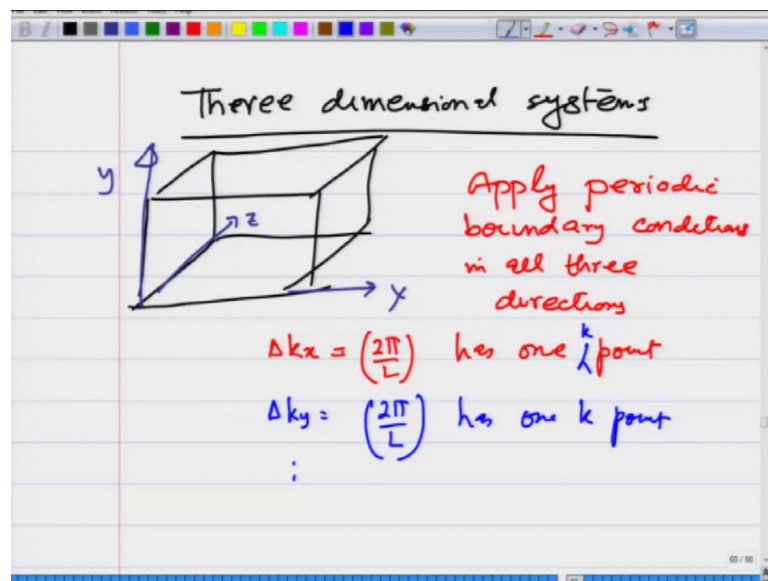

The other photons that we had was acoustic phonons. And here what we had was if I go up to  $\pi/a$ , and here is minus  $\pi/a$ , the  $\omega$  versus  $k$  graph looks like this. In this case doing a calculation with all the dispersion here  $v$   $g$  changing continuously becomes difficult. So, an approximation is made whereby I take the dispersion to be linear like this. In this case what we do is we take  $\omega$   $k$  is equal to the speed of sound times  $k$ ,

so that  $d\omega dk$  becomes  $v s$ . And density of states in one dimension becomes  $L$  over  $2\pi v s$  that is it this is known as Debye model, obviously it is an approximation.

And there has to be a maximum  $\omega_D$  or Debye there has to be a maximum  $\omega_{max}$ , so that integration  $0$  to  $\omega_D$  this is  $\omega_{max} D \omega$ ,  $D \omega$  is equal to  $N$ . Therefore, you get  $L \omega_D$  over  $2\pi v s$  equals  $N$  and  $\omega_D$  is equal to  $2\pi v s N$  divided by  $L$ . So, when I make this approximation, the Debye model for  $D \omega$  there is a maximum  $\omega_D$  up to which the modes go, because after that all the atoms all the number of modes, which are  $N$  is exhausted. So, there is a maximum frequency  $\omega_D$ , which is known as the Debye frequency. So, we have introduced a new term called  $\omega_D$ , which is Debye frequency.

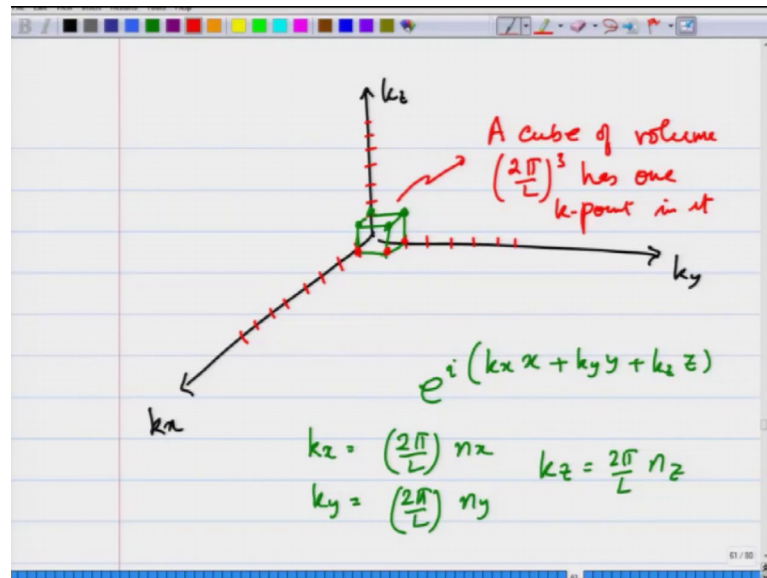

So, I have given you the idea of two models of calculating  $D \omega$  from  $dk$  Einstein model and  $D \omega$  by model in one dimension, real crystals are three-dimensional. So, now, we will work these things out for three-dimensional crystals.

(Refer Slide Time: 10:21)

So, let us now consider the case of three-dimensional systems, where the crystal extends all three-dimensions in the x-direction, in the y-direction and in the z-direction. And then we apply periodic boundary condition in all three directions, what would this give me, this will give me that  $\Delta k_x$  with  $2\pi$  over  $L$  has one point, one  $k$  point  $\Delta k_y$  equals  $2\pi$  over  $L$  has one  $k$  point and same thing for  $\Delta k_z$ .

(Refer Slide Time: 11:51)

Let me show it pictorially. So, if I have this  $k_x$ ,  $k_y$ ,  $k_z$  there is one every  $2\pi$  by  $L$  there is one  $k_x$  point, every  $2\pi$  by  $L$  there is one  $k_y$  point, every  $2\pi$  by  $L$  there is a  $k_z$  point. How so because my way the displacement is  $e$  raised to  $i k_x x + k_y y + k_z z$  minus  $\omega t$ , which I am ignoring right now. So, in general, then there will be one point also at all these corners of the cube, because  $k_x$  is equal to  $2\pi$  by  $L$  times  $n_x$ ,  $k_y$  is  $2\pi$  by  $L$   $n_y$ , and  $k_z$  is  $2\pi$  by  $L$   $n_z$ . So, every time every  $n_x$ ,  $n_y$ ,  $n_z$  integer gives me one point.

What we can say from this that I will write it here in orange a cube of volume  $2\pi$  by  $L$  cube has one  $k$  point in it right. Either I can think of it that each  $k$  point has one-eighth coming into the cube or I can surround one point by this cube around it. So, a cube of volume  $2\pi$  by  $L$  cube has one  $k$  point in it.

(Refer Slide Time: 13:41)

Density of states in k-space =

$$\frac{1}{\left(\frac{2\pi}{L}\right)^3} = \left(\frac{L^3}{8\pi^3}\right)$$
$$\mathcal{D}(k) = \frac{L^3}{8\pi^3} = \left(\frac{V}{8\pi^3}\right)$$

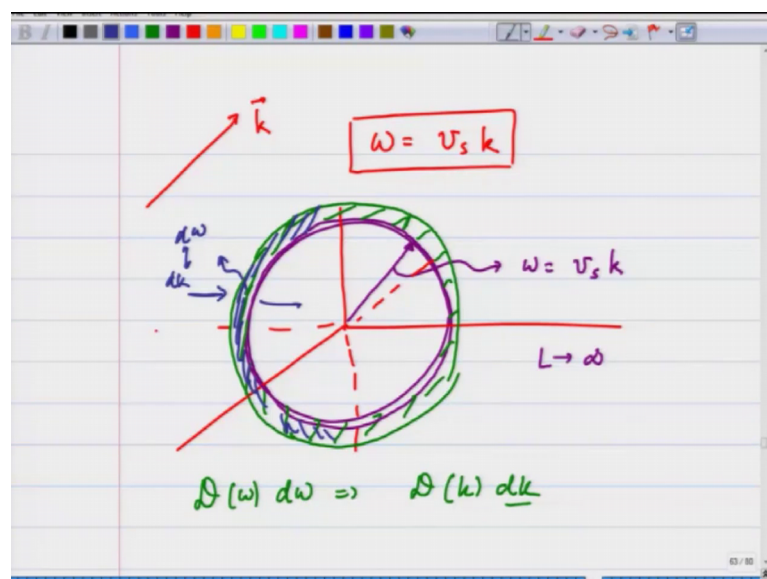

Number of modes in volume  $dk_x dk_y dk_z$

$$= \left(\frac{V}{8\pi^3}\right) dk_x dk_y dk_z$$

Get  $\mathcal{D}(\omega)$  from  $\mathcal{D}(k)$

And therefore, the density of states in k space is going to be 1 over 2 pi by L cube, which is L cubed over 8 pi cube. So, we found  $\mathcal{D} k$  to be L cubed over 8 pi cube, which is also written as L cube is the volume of the crystal over 8 pi cubed. And number of modes in volume  $dk_x, dk_y, dk_z$  is equal to  $v$  over 8 pi cubed times  $dk_x, dk_y, dk_z$ . And my next job is to get  $\mathcal{D} \omega$  from  $\mathcal{D} k$ . How do we do that, I will take a very simple calculation.

(Refer Slide Time: 15:01)

Now, recall that if there is a phonon propagating in direction  $k$ , I am going to have  $\omega = v_s k$ . I am taking things to be isotropic. And if I now look at this  $k$  space add some large value of  $k$  right,  $\omega$  is going to be given as  $v_s k$ . Recall from your lecture on 1 d that  $L$  is really going to infinity. So, these cubes are very, very small. So, if I were to look at one particular  $\omega$ , I can take this line which gives me one particular  $\omega$  to be almost spherical in fact perfectly spherical in the limit of  $L$  going to  $\infty$ . What I want to count is, what is the number of modes between  $\omega$  and  $\omega + d\omega$ , I want to count the number of modes in this shell.

And that is quite easy number of modes in this shell is going to be equal to  $D(\omega) d\omega$ , where  $D(\omega)$  corresponds to this width out here, this width out here in the radius in the  $k$  space  $d\omega$  corresponds to  $d k$ . So, what I need to do is actually count the number of modes in this volume of  $k$  space, where the radius of this the shell is  $k$  in  $k$  space, and that will give me  $D(\omega)$  in  $\omega$  space.

(Refer Slide Time: 17:01)

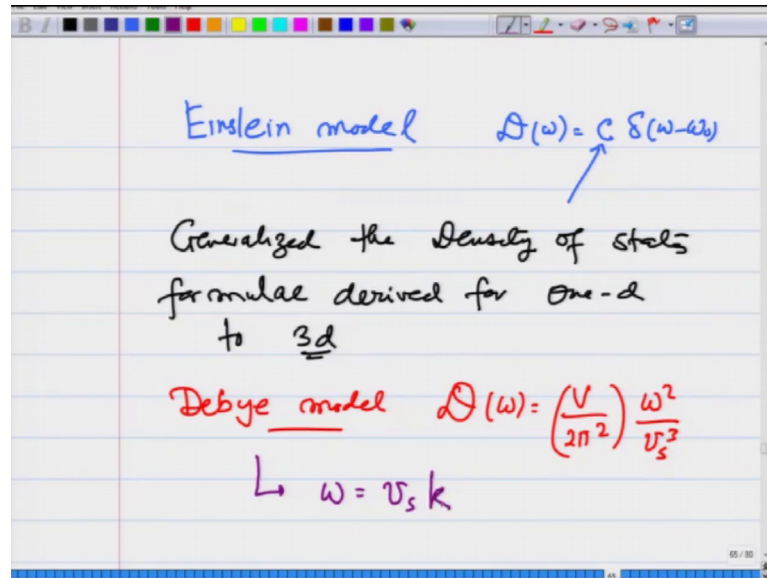

$$\begin{aligned}
 & (4\pi k^2 dk) \frac{V}{8\pi^3} \\
 & \downarrow \\
 & 4\pi \frac{\omega^2}{v_s^2} \times \frac{d\omega}{v_s} \cdot \frac{V}{8\pi^3} \\
 & = \left[ \left( \frac{\omega^2}{v_s^3} \right) \frac{V}{2\pi^2} \right] d\omega \\
 & \quad \quad \quad \underbrace{\hspace{10em}}_{D(\omega)} \\
 & D(\omega) = \left( \frac{V}{2\pi^2} \frac{\omega^2}{v_s^3} \right) \rightarrow \text{Debye Model}
 \end{aligned}$$

So, if I look at this sphere of radius  $\omega$  a correspondingly  $k$  in the  $k$  space and count the number of modes in this volume, this volume is  $4\pi k^2 dk$ , and the number of modes in this is going to be  $v_s^3 / 8\pi^3$ . Now, let us translate this into  $\omega$  space, and this comes out to be  $4\pi k^2 dk$  is nothing but  $\omega^2 / v_s^2$  times  $d\omega / v_s$  is nothing but  $d\omega / v_s$  times  $v_s^3 / 8\pi^3$ , which I can write as  $\omega^2 / v_s^3$  times  $v_s^3 / 2\pi^2 d\omega$ .

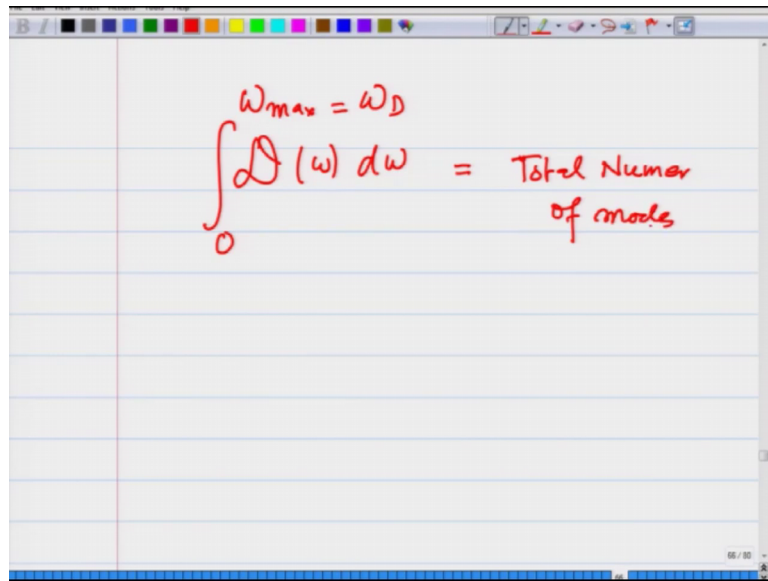

And this is nothing but by definition  $D(\omega)$ . So,  $D(\omega)$  is equal to  $v$  over  $2\pi$  square  $\omega$  square over  $v$  s cubed. And remember in this case we assume that  $\omega$  equals  $v$  s  $k$ . So, this is the Debye model.

(Refer Slide Time: 18:39)

The Einstein model in which case  $\omega$  is almost a constant remains the same, this equals you know whatever some constant times  $\delta(\omega - \omega_0)$ , I am writing this constant, because in 3D the number of modes would be different. So, what we have done in this lecture is generalized the density of states formulae derived for 1D to 3D. And in particular the Debye model, we got  $D(\omega)$  equals  $v$  over  $2\pi$  square  $\omega$  square over  $v$  sound cube. Now, what is Debye model? In this we assume that  $\omega$  is  $v$  s times  $k$ .

(Refer Slide Time: 19:57)

$$\omega_{\max} = \omega_D$$
$$\int_0^{\omega_D} D(\omega) d\omega = \text{Total Number of modes}$$

Now, obviously when I have this  $D(\omega)$ , it integrated over from some  $\omega$  equals 0 to  $\omega_{\max}$ , which I am called going to call the  $\omega_D$  Debye should integrate to the total number of modes.
