Lecture – 58
Mixing of plane waves to get Bloch Wavefunction – I

(Refer Slide Time: 00:19)

In the lecture so far what I have argued is that, given a periodic potential $V(x)$ equals $V(x+a)$ where a is the lattice parameter. The wave function has the form $\psi_k(x)$ and we label it with k equals e^{ikx} a periodic function $u_k(x)$ and this is known as the Bloch's theorem. Then once we know this general form and let me also write this for three dimensions 3-d, the Bloch's theorem says that there is a k vector r is going to be equal to $e^{i\vec{k}\cdot\vec{r}}$ $u_{\vec{k}}(\vec{r})$ where $u_{\vec{k}}(\vec{r})$ is equal to $u_{\vec{k}}(\vec{r} + \vec{R})$ plus the lattice vector \vec{r} . This is periodic with lattice vector minimum being primitive lattice vector. So, it is periodic over that. This was the effect on the wave function how about the energy.

(Refer Slide Time: 01:44)

Energy when a particle is moving
in a periodic potential?
Nearly free electron model
 $V(x)$ is weak
Perturbation theory taking
 $H^0 = -\frac{\hbar^2}{2m} \frac{d^2}{dx^2}$
 $H = H^0 + V(x)$
 $V(x) = \sum_G e^{iGx} V_G$
 $= \cancel{V_0} + \sum_{G \neq 0} e^{iGx} V_G$
0

When a particle is moving in a periodic potential, we considered what I call the nearly free electron model in which $V(x)$ is weak. And therefore, we could apply perturbation theory taking the unperturbed Hamiltonian H^0 to be only the kinetic energy operator and adding to it the weak periodic potential.

The potential has the form $V(x) = \sum_G e^{iGx} V_G$ summed over G from which I can separate the $G = 0$ component which is V_0 plus $\sum_{G \neq 0} e^{iGx} V_G$; $G = 0$ and you see this $G = 0$ component is a constant. So, it just refers to the reference point of the potential and we took this to be 0.

(Refer Slide Time: 03:32)

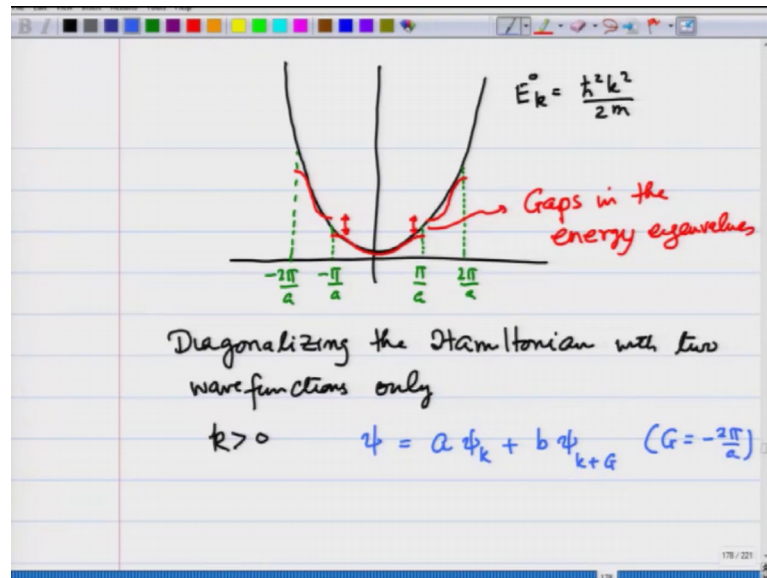

First order correction to the energy
 $E^{(1)} = V_0 = 0$

Second order correction
$$E_k^{(2)} = \sum_{G \neq 0} \frac{\langle e^{i k' x} | V_G e^{i G x} e^{i k x} \rangle}{E_k - E_{k'}}$$
$$= \sum_G \frac{|V_G|^2}{E_k - E_{k+G}}$$

When k & $(k+G)$ levels are degenerate
 $E_k^{(2)} \rightarrow \infty \Rightarrow$ Degenerate pert. theory should be applied

In that case when I applied the perturbation theory, we found that the first order correction to the energy E_1 was equal to V_0 which is 0 and the second order correction E_2 which is given as summation G naught equal to 0 E raised to $i k$ prime $\times V_G e$ raised to $i G x e$ raised to $i k x$ divided by E_k minus E_k prime; this is second order correction for the k 'th level. This comes out to be equal to $\text{mod } V_G \text{ square over } E_k \text{ minus } E_{k+G}$ summed over G . This is all fine as long as k and k plus G are not degenerate, when k and k plus G levels are degenerate, then E_2 k goes to infinity. Our perturbation result does not hold anymore and what we did then is we applied implies degenerate perturbation theory should be applied.

(Refer Slide Time: 05:25)

When we apply degenerate perturbation theory what we found is, that if I have this unperturbed energy curve like this $E_0(k) = \frac{\hbar^2 k^2}{2m}$. At the points, the Brillouin zone let me make two of them. This is $\frac{\pi}{a}$ over 2π over a , minus π over a , minus 2π over a . This is where E_k and E_{k+G} become degenerate.

For example for $k = \frac{\pi}{a}$ $E_k - \frac{2\pi}{a}$ will become degenerate for $k = \frac{2\pi}{a}$ $2\pi/a - 4\pi/a$ will become degenerate and then what happens is that a gap opens up near the Brillouin zone boundary. And therefore, energy does not remain continuous anymore rather it will become something like this and there is this gap which opens up. So, you have gaps in the energy. So, these are called the gaps in the energy eigenvalues. These energies are not there anymore and we got this by applying degenerate perturbation theory.

Let us now look at this result from the point of view of diagonalizing the Hamiltonian with two wave functions only. I will consider case where $k > 0$. So, I am considering the case where I am on the right side of $k = 0$ and I will consider the wave function side to be some constant $a\psi_k$ plus where ψ_k is understood by E_k raised to $i k x + b\psi_{k+G}$. We are now in this case because I am taking $k > 0$ G should be equal to $-\frac{2\pi}{a}$ because the degeneracy opens up at $k = \frac{\pi}{a}$. So, I am mixing these two levels and seeing what the energy would look like.

(Refer Slide Time: 08:11)

$$\psi = a e^{ikx} + b e^{i(k-\frac{2\pi}{a})x}$$

Write the Schrodinger equation

$$H\psi = E\psi$$

$$-\frac{\hbar^2}{2m} \frac{d^2\psi}{dx^2} + \left(\sum_{G \neq 0} V_G e^{iGx} \right) \psi = E\psi$$

$$\frac{\hbar^2 k^2}{2m} e^{ikx} a + \frac{\hbar^2 (k-\frac{2\pi}{a})^2}{2m} e^{i(k-\frac{2\pi}{a})x} b + \sum_{\substack{G \\ G \neq 0}} V_G e^{i(G+k)x} a + \sum_{\substack{G \\ G \neq 0}} V_G e^{i(G+k-\frac{2\pi}{a})x} b = E e^{ikx} a + E e^{i(k-\frac{2\pi}{a})x} b$$

So, let me write it explicitly I am looking at psi equals a e raised to i k x plus b e raised to i k minus 2 pi by a x. If I now write the Schrodinger equation, then I have H psi equals E psi and I have h s minus h cross square over 2 m d 2 psi over d x square plus summation V G G naught equal to 0 E raised to i G x times psi equals E psi.

So, let me now apply this two psi and then I am going to have h cross square k square over 2 m w raised to i kx will come with a coefficient a plus h cross square k minus 2 pi by a square over 2 m e raised to i k minus 1 pi by a x come with the coefficient b plus summation G V G E raised to i G plus k x. This will come with a coefficient a G is not equal to 0 plus summation G V G e raised to i G plus k minus 2 pi by a x, this is also G naught equal to 0 equals E e raised to i kx with a coefficient a plus E e raised to i k minus 2 pi by a x b. This is the equation that we get for a and b. In this I will equate the coefficients of e raised to i kx on both sides e raised to i k minus 2 pi by a on both sides

So, you can see since G is not equal to 0, I will get G equals minus 2 pi by a here and that will give me the coefficient for k minus 2 pi by a x and I will have G equals 2 pi by a here and that will give me the coefficient for E raised to i kx.

(Refer Slide Time: 11:31)

$$E_k^0 \left(\frac{\hbar^2 k^2}{2m} \right) a - E a + b V_{\frac{2\pi}{a}} = 0$$

$$V_{-\frac{2\pi}{a}} a + \left(\frac{\hbar^2 (k - \frac{2\pi}{a})^2}{2m} \right) b - E b = 0$$

If a & b are to be non-zero

$$\begin{vmatrix} (E_k^0 - E) & V_G \\ V_G & (E_{k+G}^0 - E) \end{vmatrix} = 0$$

So, equating the coefficients of e raised to ikx and e raised to $ikx - 2\pi$ by a , I get $\frac{\hbar^2 k^2}{2m} a - E a + b V_{\frac{2\pi}{a}} = 0$ and for the other equation, I get I will write the part first.

So, I am going to get $V_{-\frac{2\pi}{a}} a + \frac{\hbar^2 (k - \frac{2\pi}{a})^2}{2m} b - E b = 0$. If a and b are to be non-zero, then I should have the determinant of let me write this term as E_k^0 and this term as E_{k+G}^0 . So, that I get $E_k^0 - E$. Here I am going to get V_G is $V_{\frac{2\pi}{a}}$. So, V_G V_G $E_{k+G}^0 - E$ determinant should be 0 and that will give me the eigenvalue E .

(Refer Slide Time: 13:30)

$$(E_k^0 - E)(E_{k+G}^0 - E) - |V_G|^2 = 0$$

$$V_G = V_G^*$$

$$E^2 - (E_k^0 + E_{k+G}^0)E + (E_k^0 E_{k+G}^0 - |V_G|^2) = 0$$

$$E = \frac{(E_k^0 + E_{k+G}^0) \pm \sqrt{(E_k^0 + E_{k+G}^0)^2 - 4 E_k^0 E_{k+G}^0 + 4 |V_G|^2}}{2}$$

$$E_{(n)}^{(1)} = \frac{E_k^0 + E_{k+G}^0}{2} \pm \sqrt{\frac{(E_k^0 - E_{k+G}^0)^2}{4} + |V_G|^2}$$

Let us solve this. When I solve this, I am going to get $E_k^0 - E$ times $E_{k+G}^0 - E$ minus $|V_G|^2$ is equal to 0. This comes out to be $|V_G|^2$ because V_{-G} is equal to V_G^* and this equation then becomes $E^2 - (E_k^0 + E_{k+G}^0)E + (E_k^0 E_{k+G}^0 - |V_G|^2) = 0$. This is a quadratic equation in E .

So, the solutions for E are $E_k^0 + E_{k+G}^0$ plus or minus square root of $(E_k^0 + E_{k+G}^0)^2 - 4 E_k^0 E_{k+G}^0 + 4 |V_G|^2$ divided by 2. And therefore, I get two solutions E_1 is equal to $(E_k^0 + E_{k+G}^0) / 2 + \sqrt{(E_k^0 - E_{k+G}^0)^2 / 4 + |V_G|^2}$. I can write 2 here for the lower side plus or minus square root of $(E_k^0 - E_{k+G}^0)^2 / 4 + |V_G|^2$. And deriving this, I have taken this 2 inside the square root sign and therefore, it goes as 1 over 4 and this is what we get.

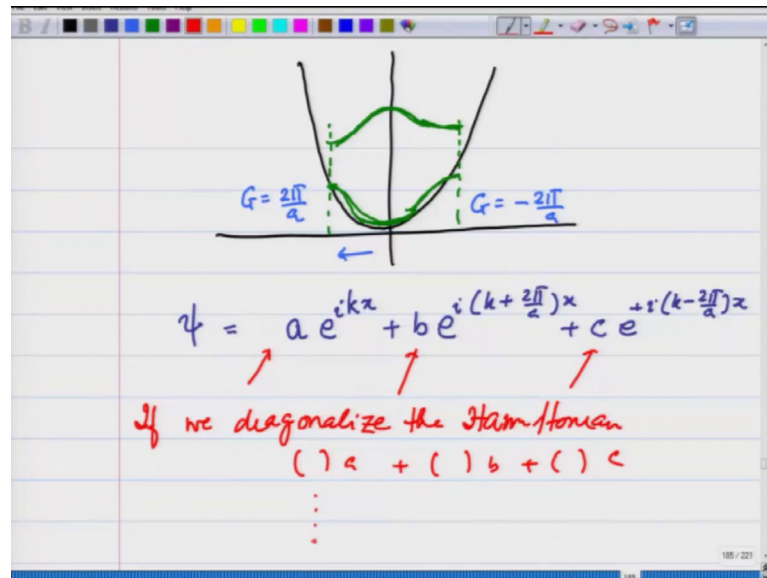

(Refer Slide Time: 15:39)

The image shows a whiteboard with handwritten mathematical equations and text. At the top, the energy level $E_{(1)}^{(1)}$ is given as $\frac{E_k^0 + E_{k+G}^0}{2} \pm \sqrt{\frac{(E_k^0 - E_{k+G}^0)^2}{4} + |V_G|^2}$. Below this, it says "The potential is weak $|V_G|$ is small". Two cases are listed: (i) $(E_k^0 - E_{k+G}^0)^2 \gg 4|V_G|^2$ leading to $E_{(1)}^{(1)} = E_k^0$ or E_{k+G}^0 ; and (ii) $|V_G|^2 \gg \frac{1}{2}(E_k^0 - E_{k+G}^0)^2$ leading to $E_{(1)}^{(1)} = \frac{E_k^0 + E_{k+G}^0}{2} \pm |V_G|$. The whiteboard also has a toolbar at the top and a page number "104 / 221" at the bottom right.

So, what we have is that $E_{1 \text{ or } 2}$ is equal to E_k^0 plus E_{k+G}^0 divided by 2 plus or minus square root of $(E_k^0 - E_{k+G}^0)^2$ divided by 4 plus $|V_G|^2$. Now since V the potential is weak, V_G can be very small is small. Now take two cases; 1, $(E_k^0 - E_{k+G}^0)^2$ is much much much greater than $4|V_G|^2$.

In that case I am going to get $E_{1 \text{ or } 2}$ is equal to E_k^0 or E_{k+G}^0 not much different. It is like first order perturbation theory where the first order correction was 0, second order correction is small. On the other hand, if I take $|V_G|^2$ to be much much greater than $\frac{1}{2}(E_k^0 - E_{k+G}^0)^2$; that means, I am reaching the regime of the points where E_k^0 and E_{k+G}^0 are very close. I am reaching near the Brillouin zone, then I get $E_{1 \text{ or } 2}$ is equal to $\frac{E_k^0 + E_{k+G}^0}{2}$ plus or minus $|V_G|$. Precisely is the result that we got through degenerate perturbation theory.

(Refer Slide Time: 17:52)

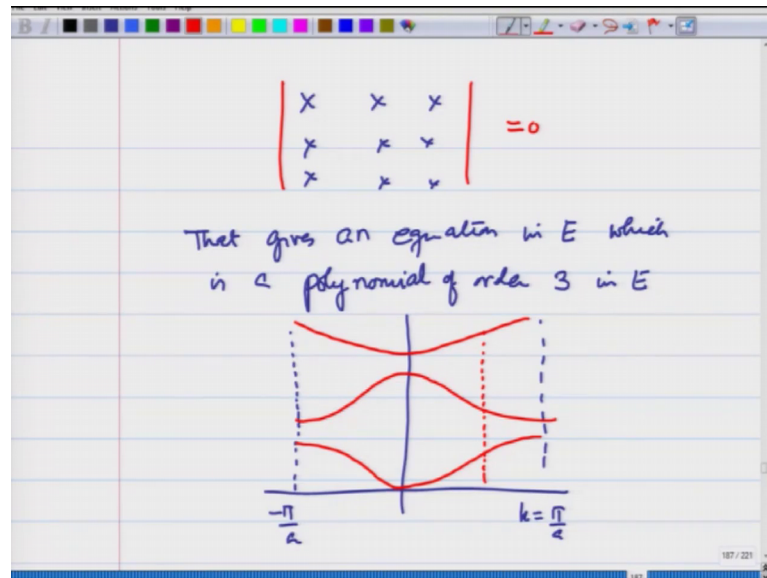

So, this again tells you that if I have this energy curve near k equals 0 or so, the energy remains roughly either $E(k=0)$ or $E(k)$. I will show you how this curve comes later $E(k) + G(0)$ and as you approach the Brillouin zone, there is a gap that opens up as you approach the Brillouin zone, there is a gap that opens up.

So, energy curves look like this. Besides the result we got earlier, this we did through two plane waves mixing. Now for this, I had to take G equals minus $2\pi/a$ when I was going towards the right and I will have to take G equals $2\pi/a$ when I was going towards the left. This part I did not do, but you can easily see since everything is symmetric; you can repeat this calculation. So, I had to take G equals $2\pi/a$ when I was considering k on this side.

Suppose I do not want to do that I do not want to consider which G to take which not to take. I will take an expansion where I will take ψ to be a mixture of three plane waves $e^{ikx} + b e^{i(k + 2\pi/a)x} + c e^{i(k - 2\pi/a)x}$. I do not have to now worry whether I am taking G equals plus $2\pi/a$ minus $2\pi/a$ and so on and again repeat the same calculation.

Now, I have three coefficients. So, I will have an equation for these three coefficients and if we diagonalize the Hamiltonian, I will have three equations; some coefficient a plus, some coefficient b plus some coefficient c three equations like these and for a, b, c to be nonzero, the determinant of these coefficients will have to be 0.

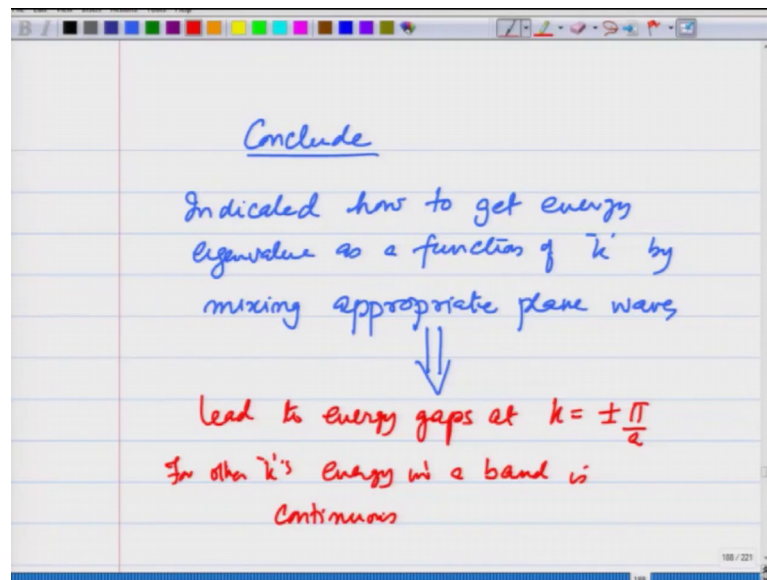

(Refer Slide Time: 20:10)

And that will give. So, these are the coefficients and that gives an equation in E or for E which is a polynomial of order 3 in E. And then you will have to calculate the eigenvalues of E through a computer and what you will find and this I will give as an assignment. Again if I can find myself between k equals π by a and $-\pi$ by a , you will find that you will get energy for different case like this and there will be a band like this. So, you will get 3 eigenvalues for each k because I mix three plane waves and you will find a band structure like this.

More plane waves I add, more the bands you will get and I will do that in the next lecture and you will also see why I am confining myself to $-\pi$ by 2π by a .

(Refer Slide Time: 21:31)

So, we conclude in this lecture, what I have done is indicated how to get energy eigenvalue as a function of k by mixing appropriate plane waves. And these also lead to energy gaps at k equals plus minus π by a , for other case energy in a band is continuous. I will build upon this argument in the next lecture and give a proof based on this plane wave expansion give a proof for the Blochs theorem again.
