Lecture – 59
Mixing of plane waves to get Bloch wavefunction – II

(Refer Slide Time: 00:13)

$$\psi(x) = a e^{ikx} + b e^{i(k+G)x}$$

$$G = \pm \frac{2\pi}{a}$$

$$\psi(x) = a e^{ikx} + b e^{i(k - \frac{2\pi}{a})x} + c e^{i(k + \frac{2\pi}{a})x}$$

$$\psi(x) = \sum_{\mathbf{k}} c(\mathbf{k}) e^{i\mathbf{k}x}$$

$$\mathbf{k} \rightarrow \mathbf{k} + \mathbf{G}$$

In the previous lecture I took $\psi(x)$ to be $a e^{ikx} + b e^{i(k+G)x}$, where G was $2\pi/a$ plus or minus and showed how I can get energy bands or energy gaps. Then I also showed you if I take $\psi(x)$ to be equal to a combination of three plane waves $a e^{ikx} + b e^{i(k - 2\pi/a)x} + c e^{i(k + 2\pi/a)x}$ how I can get 3 bands? And this I will also give you as an assignment problem.

Now, we generalize this and think of what happens if I take $\psi(x)$ to be a combination of many many many different case. How do these plane waves couple from the two exercises that I have just mentioned? You can see that k will couple with $k + G$ where G could be $2\pi/a$, $4\pi/a$, $-2\pi/a$, $-4\pi/a$ and so on. However, now we are going to prove it and this is also lead to another proof of Bloch's theorem. So, let us look at the Schrodinger equation.

(Refer Slide Time: 01:38)

$$H = -\frac{\hbar^2}{2m} \frac{d^2}{dx^2} + \sum_{G \neq 0} V_G e^{iGx}$$
 Assume that e^{ikx} is its solution

$$H e^{ikx} = E e^{ikx}$$

$$\frac{\hbar^2 k^2}{2m} e^{ikx} + \sum_{G \neq 0} V_G e^{i(k+G)x} = E e^{ikx}$$

$$\left(\frac{\hbar^2 k^2}{2m} - E \right) + \sum_{G \neq 0} V_G e^{iGx} = 0$$
 } e^{ikx} is not the solⁿ
 \uparrow $H\psi = E\psi$

H the Hamiltonian is minus h cross square d 2 by d x square over 2 m here plus summation G and we have taken G not equal to 0 V G e raised to i G x. Assume that e raised to i k x is its solution and substitute it in the Schrodinger equation. So, I take H e raised to i k x is equal to E, e raised to i k x; then I find that I have h cross square k square over 2 m, e raised to i k x plus summation over G; G not equal to 0; V G e raised to i, k plus G x is equal to E e raised to i k x.

What you notice is because of these V G's not being 0 this equation cannot be satisfied because I have e raised to i k x on this side, e raised to i k x on this side which I can cancel from the two sides. And then get h cross square k square over 2 m minus E plus summation G; V G e raised to i, G x is equal to 0. This is a constant; so it tells you either the potential itself is 0 and in that case e will be equal to H cross k square over 2 m; if potential is not 0 then this equation certainly is not satisfied.

And therefore, we have to do something e raised to i k x cannot be the solution. So, we conclude from here that e raised to i k x is not the solution of H psi equals E psi or the Schrodinger equation.

(Refer Slide Time: 03:52)

$$\frac{\hbar^2 k^2}{2m} e^{ikx} + \sum_{G \neq 0} V_G e^{i(k+G)x} = E e^{ikx}$$
$$e^{ikx} + e^{i(k+G)x} \text{ for all } G$$
$$\psi(x) = \sum_G e^{i(k+G)x} C(G)$$

$C(G)$ are expansion coefficients

$$\psi(x) = \sum_G C(G) e^{i(k+G)x}$$

So, what did we have? Let us rewrite it; $\frac{\hbar^2 k^2}{2m} e^{ikx} + \sum_{G \neq 0} V_G e^{i(k+G)x} = E e^{ikx}$. What you notice is that when I have this e^{ikx} here the other terms $e^{i(k+G)x}$ also popping they start coming in.

So, if I want to satisfy this equation on both sides; what I should have is for each e^{ikx} , I should also add to it $e^{i(k+G)x}$ for all reciprocal space vectors G . And therefore, I should take the solution $\psi(x)$ to be equal to $\sum_{G \neq 0} e^{i(k+G)x} C(G)$; where $C(G)$ are expansion coefficients.

And notice with k I am adding only e^{ikx} I am adding only $e^{i(k+G)x}$ because of this specific nature or periodicity of the potential. I cannot add anything else if I substitute anything else here, again the equation will not be satisfied. So, now let us substitute this $\psi(x)$ and see what we get. So, I am going to get the wave function $\psi(x)$ which is equal to $\sum_G C(G) e^{i(k+G)x}$.

(Refer Slide Time: 05:48)

$$\begin{aligned}
 H\psi &= E\psi \\
 \sum_G \frac{\hbar^2(k+G)^2}{2m} e^{i(k+G)x} C(G) &+ \sum_{G'} \sum_G V_{G'} C(G) e^{i(G'+G+k)x} \\
 &= \sum_G E e^{i(k+G)x} C(G) \\
 \sum_G \left(\frac{\hbar^2(k+G)^2}{2m} - E \right) C(G) e^{i(k+G)x} &+ \sum_{G, G'} V_{G'} C(G) e^{i(G'+G+k)x} = 0
 \end{aligned}$$

And when I substituted this in $H\psi = E\psi$; I am going to get summation G $\frac{\hbar^2(k+G)^2}{2m} e^{i(k+G)x} C(G)$ plus for the potential I have to now write G' ; summation G $V_{G'} C(G) e^{i(G'+G+k)x}$ equals $E e^{i(k+G)x} C(G)$ summed over G ; these are different terms.

So, now let us bring everything to the left hand side. So, I am going to get summation G $\frac{\hbar^2(k+G)^2}{2m} - E$ $C(G) e^{i(k+G)x}$ plus summation over G, G' $V_{G'} C(G) e^{i(G'+G+k)x}$ is equal to 0. Let us now equate the coefficients corresponding to each $e^{i(k+G)x}$ on both sides.

(Refer Slide Time: 07:44)

$$\sum_G \left(\frac{\hbar^2 (k+G)^2}{2m} - E \right) c(G) e^{i(k+G)x} + \sum_G \sum_{G'} V_{G'} e^{i(k+G+G')x} c(G) = 0$$

If we look at the coefficient of $e^{i(k+G)x}$

$$\left(\frac{\hbar^2 (k+G)^2}{2m} - E \right) c(G) + \sum_{G'} c(G-G') V_{G'} c(G-G')$$

So, this equation is $\hbar^2 (k+G)^2 / 2m - E$ $c(G) e^{i(k+G)x}$ plus $\sum_G \sum_{G'} V_{G'} e^{i(k+G+G')x} c(G) = 0$; this is also a summation over G .

If we look at the coefficient of $e^{i(k+G)x}$; then in the first term this term it is $\hbar^2 (k+G)^2 / 2m - E$. And in this term the second term the G ; they will appear would be actually I want $e^{i(k+G'')x}$ and therefore, I should have $G'' = G - G'$ the term that will be picked up will be let me call it $G'' = G - G'$.

So, that I will have $V_{G'} e^{i(k+G''+G')x} c(G-G')$ where $G'' = G - G'$. So, I get the equation $\hbar^2 (k+G)^2 / 2m - E$; $c(G) + \sum_{G'} c(G-G') V_{G'} c(G-G')$. And all these give me the coefficient $c(G-G')$ and $e^{i(k+G'')x}$; for all G' , so any G' I can pick $G - G'$ as G'' right.

So, then this should all be 0; let me rewrite this whole thing.

(Refer Slide Time: 10:50)

$$\left(\frac{\hbar^2 (k+G)^2}{2m} - E\right) C(G) e^{i(k+G)x} + \sum_{\substack{G' \\ G' \neq 0}} V_{G'} C(G-G') e^{i(k+G-G')x} = 0$$

Coefficients of $e^{i(k+G)x} = 0$

$$\left(\frac{\hbar^2 (k+G)^2}{2m} - E\right) C(G) + \sum_{G'} V_{G'} C(G-G') = 0$$

(1) $C(G)$ gets coupled with $C(G-G')$
i.e. a coeff for $e^{i(k+G)}$ gets coupled
only to coeff for $e^{i(k+G-G')}$

The equation I have is $\frac{\hbar^2 (k+G)^2}{2m} - E$; $C(G)$ plus summation over G and G' $V_{G'}$; keep in mind the G' is not equal to 0; $C(G-G')$ $e^{i(k+G-G')x}$ is equal to 0, here is $e^{i(k+G)x}$.

Now I want because these are all independent functions $e^{i(k+G)x}$; I want the coefficient of $e^{i(k+G)x}$ to be 0. And therefore, I am going to have $\frac{\hbar^2 (k+G)^2}{2m} - E$; $C(G)$ plus summation over G' ; $V_{G'}$ $C(G-G')$. For each $V_{G'}$ I pick up a coefficient $C(G-G')$ and this is equal to 0. This is the equation that determines coefficient C and $C(G-G')$.

You notice one thing here that $C(G)$ gets coupled with $C(G-G')$. That is a coefficient for $e^{i(k+G)x}$ gets coupled only to coefficient for $e^{i(k+G-G')x}$; that is the k which is displaced by it from it by another lattice vector.

(Refer Slide Time: 03:17)

$\Rightarrow e^{i(k+G)x}$ gets mixed with only $e^{i(k+G-G')x}$

$$\psi_k(x) = c(k)e^{ikx} + \sum_G c(k+G)e^{i(k+G)x}$$

Notice that $\psi_k(x)$ satisfies the property that

$$\psi_k(x+a) = c(k)e^{ik(x+a)} + \sum_G c(k+G)e^{i(k+G)(x+a)}$$

$$e^{iGa} = 1$$

This implies $e^{i(k+G)x}$ gets mixed with only $e^{i(k+G-G')x}$.

So, only those plane waves mix that have a difference of G that is another lattice vector from each other. So, the wave function is going to be $\psi_k(x)$ is equal to; let me now separate out $G=0$. Some coefficient C_k ; e^{ikx} plus summation over G . Now I am going to label it as C_{k+G} ; $e^{i(k+G)x}$. Earlier I had not written C_k it was just C_G ; so k was 0 and then G ; now I am specifically writing this k because k gets mixed only with $k+G$ not any other k .

So, I can actually label this wave function as being specified by k . These are the wave functions and notice that $\psi_k(x)$ satisfies the property that $\psi_k(x+a)$ is going to be equal to $C_k e^{ik(x+a)} + \sum_G C_{k+G} e^{i(k+G)(x+a)}$. Now e^{iGa} is equal to 1.

(Refer Slide Time: 15:16)

$$\psi_k(x+a) = e^{ik a} [\psi(x)]$$

It satisfies \nearrow Bloch's theorem

$$\psi_k(x) = e^{ikx} \left[\sum_G c(k+G) e^{iGx} \right]$$

a function periodic with periodicity $\frac{2\pi}{G} = a$

Therefore $\psi_k(x+a)$ becomes $e^{ik a}$ times whatever that summation is left is $\psi_k(x)$.

So, it satisfies this property and that is Bloch's theorem. You can also see that I can write $\psi_k(x)$ as; if I take e^{ikx} out I have summation. I can write this as $\sum_G c(k+G) e^{iGx}$. $G=0$ is also included because C_k is included here and this is a function periodic with periodicity $\frac{2\pi}{G}$ which is a ; so, this is another way of writing the Bloch's theorem.

(Refer Slide Time: 16:41)

$$\psi(x) = \sum_k c(k) e^{ikx}$$

$$\left(\frac{\hbar^2 k^2}{2m} - E \right) c(k) + \sum_{G'} V_{G'} c(k-G') = 0$$

$$\left(\frac{\hbar^2 (k+G)^2}{2m} - E \right) c(k+G) + \sum_{G'} V_{G'} c(k+G-G') = 0$$

Three plane waves

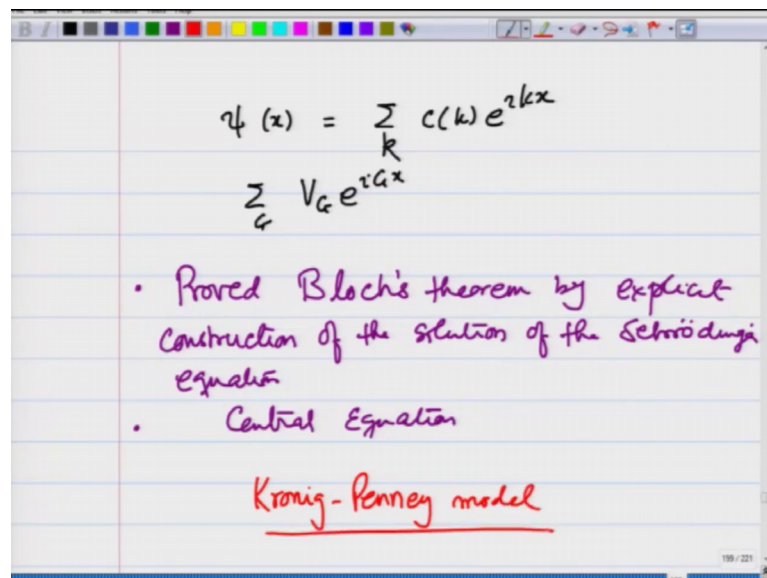

Central Equation.

So, what we found is that when I turn this periodic potential on the wave function is of the form it can be labeled by a k equals summation I can now write G ; G equals 0 included C_k plus G $e^{i(k+G)x}$. And C_k satisfies C_k $h^2 k^2$ over $2m$ minus E plus summation G prime; V_G C_{k-G} minus C_k equals 0, this equation can also be written for each other C_k .

So, I can write $h^2 k^2$ over $2m$ minus E ; C_k plus G plus summation G prime V_G C_{k+G} minus C_k is equal to 0. Again at G prime equals $-G$ the C_k will come here. So, this is a set of equations for all C_k and if you want to now calculate the energy, you have to take a finite number of these equations and diagonalize; the resulting determinant for the coefficients of C_k and that leads to the bands. Example of this we have already done three plane waves, were mixed and you got a model for the calculating energy in the previous lecture. I can mix 4, 5, 6 whatever number and then make a determinant and solve it.

So, this is the way the band structure is gotten by mixing plane waves this is the way that Bloch's theorem is also proved this by the way is known as the central equation.

(Refer Slide Time: 18:58)

Some of the books also bring this equation by writing $\psi(x)$ as summation over all k ; C_k e^{ikx} substitute this in the Schrodinger equation and then bring the same equation back realizing that V_G e^{iGx} summation over G is the periodic potential and therefore, only k and k plus G and all those terms come into the picture.

So, what I have done in this lecture is proved Bloch's theorem by explicit construction of the solution of the Schrodinger equation. And also as a result got the central equation which when diagonalized gives you the energy eigenvalues or depends; in all this we have to solve a determinant which is of finite order.

Now, infinite order, but we have to make it finite; in the next lecture I am going to solve a model which can be solved exactly to obtain the energy structure and in this model which is known as the Kronig Penney model. And that can be solved exactly and you will see how it leads to energy bands and so it gives a good idea about what happens when electrons move in a periodic potential. So, I will stop this lecture here next lecture we solve Kronig Penney model which is an exactly soluble model.
