Lecture - 63
Kronig- Penney model

So, far I have talked about Bloch's theorem, bands arising and also explained a bit about how band theory explains metals, insulators and semiconductors.

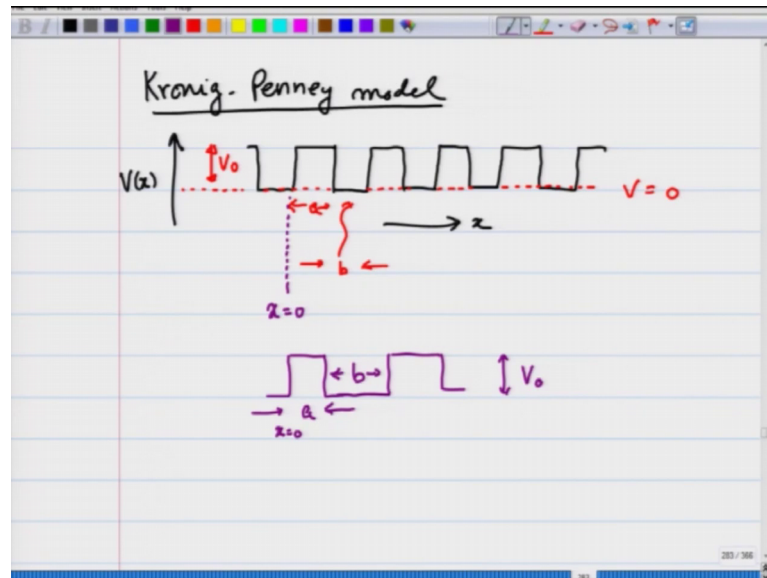

(Refer Slide Time: 00:38)

The image shows a digital whiteboard with handwritten mathematical expressions and text. At the top, the Bloch wave function is given as $\psi_{\vec{k}}(\vec{r}) = \sum_{\vec{G}} c_{\vec{k}}(\vec{G}) e^{i(\vec{k} + \vec{G}) \cdot \vec{r}}$. Below this, the text "One-d" is written in blue. Then, the 1D version of the wave function is given as $\psi_{\vec{k}}(x) = \sum_{\vec{G}} c_{\vec{k}}(\vec{G}) e^{i(\vec{k} + \vec{G})x}$. At the bottom, the text "Kronig-Penney model" is written in red and underlined, with "One-dimensional model" written below it in red.

While getting the bands, what I had done was I had expanded $\psi_{\vec{k}}(\vec{r})$ as summation $\sum_{\vec{G}} c_{\vec{k}}(\vec{G}) e^{i(\vec{k} + \vec{G}) \cdot \vec{r}}$ for \vec{k} th we have $e^{i(\vec{k} + \vec{G}) \cdot \vec{r}}$. This showed both Bloch's theorem as well as we used it for getting the bands and you have done it in your assignment also. We did other calculations in one d where $\psi_{\vec{k}}(x)$ was expanded I should write a vector here a summation $\sum_{\vec{G}} c_{\vec{k}}(\vec{G}) e^{i(\vec{k} + \vec{G})x}$ where \vec{G} was the reciprocal space vector and through this then we showed the one d Bloch's theorem as well as we got the bands also. In the assignment the problem that you have done is by mixing 3 plane waves.

In this lecture I want to solve an exact model again to show you the bands arising through Bloch's theorem. So, what I am going to do in this lecture is solve the Kronig-Penney model which is a one-dimensional model that shows how bands arise. So, we are looking at the band picture from another point of view.

(Refer Slide Time: 02:24)

So, in the Kronig- Penney model we take a one dimensional potential which is of this form it is square well and barriers extending from minus infinity to plus infinity, what I am plotting here is along x direction I am plotting the potential V x . We can take this line red line that I am drawing red dashed line to be V equals 0. The height of the barriers to be V_0 and the width to be a for the barrier and b for the well and we want to solve for the energy Eigen value and the wave function in nutshell I want to solve the Schrodinger equation for this.

So, let me take this point to be x equals 0, so let me make the potential again from x equals 0 onwards. So, I have at x equals 0 extending from 0 to a . The potential barrier and then from a to b . The potential well and the height of the potential is V_0 . So, I want to show you how Bloch's theorem is used to solve the Schrodinger equation in this particular case then we will simplify the model and solve it.

(Refer Slide Time: 04:18)

The image shows a digital whiteboard with handwritten notes. At the top, there is a diagram of a potential well. The well has a width labeled 'a' and a depth labeled 'b'. Below the diagram, the text reads 'Schrödinger equation for $0 \leq x \leq a$ '. The equation is written as $-\frac{\hbar^2}{2m} \frac{d^2\psi}{dx^2} + V_0\psi = E\psi$. Below this, it is noted that $(V_0 > E)$ and the equation is rearranged to $\frac{\hbar^2}{2m} \psi'' - (V_0 - E)\psi = 0$. This is further simplified to $\psi'' - \alpha^2\psi = 0$. Finally, the solution is given as $\psi(x) = Ae^{\alpha x} + Be^{-\alpha x}$, where $\alpha^2 = \frac{2m(V_0 - E)}{\hbar^2}$.

So, when I look at this potential extending from x equals 0 further down, so this is difference a and this is b . The Schrodinger equation for x between 0 and a is going to be minus h cross square over $2m$ $d^2\psi$ over dx^2 plus $V_0\psi$ equals $E\psi$. I will assume V_0 to be greater than E and then I have h cross square over $2m$ ψ'' minus $V_0 - E$ ψ equals 0. That is the equation and I can transform this equation into ψ'' minus $\alpha^2\psi$ equals 0.

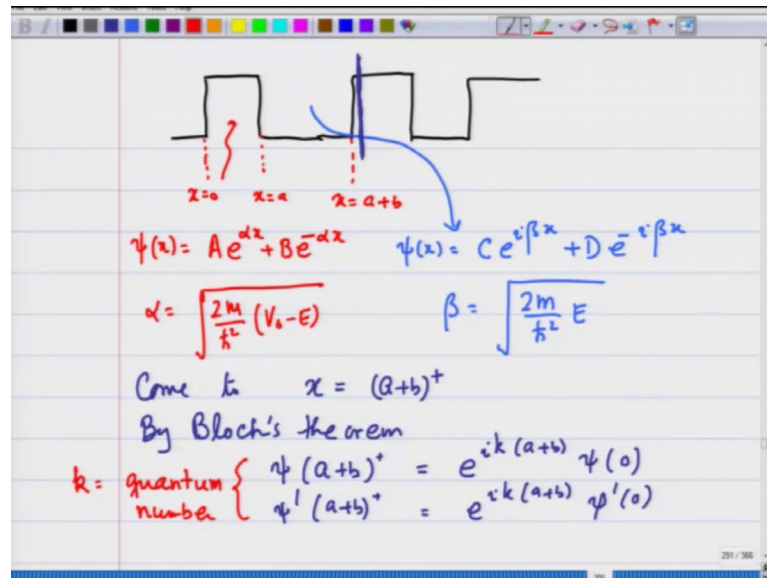

Where α^2 is $2m(V_0 - E)$ over h cross square notice that I have taken V_0 to be greater than E , therefore α^2 is a positive number and this gives me solutions $\psi(x) = Ae^{\alpha x} + Be^{-\alpha x}$. So, I obtain the solution in the region between 0 and a .

(Refer Slide Time: 06:10)

The image shows a digital whiteboard with a potential energy diagram at the top. The potential is zero for $x < a$ and $x > a+b$, and has a constant value V_0 for $a < x < a+b$. The region $a < x < a+b$ is shaded in blue. Below the diagram, the wave function for the first region is given as $\psi(x) = Ae^{\alpha x} + Be^{-\alpha x}$, with $\alpha = \sqrt{\frac{2m}{\hbar^2}(V_0 - E)}$. For the second region, $a < x < (a+b)$, the Schrodinger equation is written as $-\frac{\hbar^2}{2m}\psi'' + (V=0)\psi = E\psi$, which simplifies to $\psi'' + \frac{2mE}{\hbar^2}\psi = 0$ for $E > 0$. The solution for this region is given as $\psi(x) = Ce^{i\beta x} + De^{-i\beta x}$.

So let me make this potential again. And in this region I have got $\psi(x)$ equals $Ae^{\alpha x} + Be^{-\alpha x}$, where α is equal to $\sqrt{\frac{2m}{\hbar^2}(V_0 - E)}$. Now for the region x greater than a and less than $a + b$, that is in this region which I am showing by blue shaded lines. In this region the Schrodinger equation is $-\frac{\hbar^2}{2m}\psi'' + V = E\psi$, so this term does not exist is equal to $E\psi$. So, I get $\psi'' + \frac{2mE}{\hbar^2}\psi = 0$. Keep in mind that E is greater than 0, because lowest potential energy is 0 and therefore I get solution for this region $\psi(x)$ equals $Ce^{i\beta x} + De^{-i\beta x}$. That is the solution in the second region.

(Refer Slide Time: 07:42)

Let me show it again that when I take this potential in this region between x equals 0, x equals a and this is x equals a plus b , here on the left the wave function ψ x is equal to $A e$ raise to αx plus $B e$ raise to minus αx . In the region next to it I have ψ x equals $C e$ raise to $i \beta x$ plus $D e$ raise to minus $i \beta x$, where α is equal to square root of $2 m$ over \hbar cross square V naught minus E and β is equal to $2 m$ over \hbar cross square E square root, so far no Bloch's theorem has been used.

Now, you will see how Bloch's theorem determines the energy. If I come to x equals a plus b plus that is a point slightly outside x equals a plus b let me show this by this vertical line on the figure right here, right slightly to the right of x equals a plus b . Then by Bloch's theorem I would have ψ at x equals a plus b plus is equal to e raise to $i k$ a plus b ψ at 0 and similarly ψ prime at a plus b plus would be equal to e raise to $i k$ a plus b ψ prime at 0 that is using the Bloch's theorem and k is my is the quantum number that specifies the state ψ k .

(Refer Slide Time: 10:28)

The image shows a whiteboard with handwritten mathematical derivations. At the top, three regions are defined: $0 \leq x \leq a$, $a \leq x \leq a+b$, and $x = (a+b)^+$. For each region, a wave function $\psi(x)$ is given. In the first region, $\psi(x) = Ae^{\alpha x} + Be^{-\alpha x}$. In the second region, $\psi(x) = Ce^{i\beta x} + De^{-i\beta x}$. At the boundary $x = (a+b)^+$, the wave function is expressed as $\psi(a+b)^+ = e^{ik(a+b)} \psi(0)$, which is further simplified to $e^{ik(a+b)}(A+B)$. The derivative at this boundary is $\psi'(a+b)^+ = e^{ik(a+b)} \psi'(0) = e^{ik(a+b)}(\alpha A - \alpha B)$. Below these, two equations are derived by equating the wave function and its derivative from the left and right sides of the boundary. Equation (i) is $Ce^{i\beta(a+b)} + De^{-i\beta(a+b)} = \psi(a+b)^+ = e^{ik(a+b)}(A+B)$. Equation (ii) is $\psi'(a+b)^+ = \alpha e^{ik(a+b)}(A-B)$. At the bottom, the derivative of the wave function in the second region is given as $i\beta(Ce^{i\beta(a+b)} - De^{-i\beta(a+b)})$.

So, I have in the region x greater than 0 less than a , I have wave function $\psi(x)$ equals $Ae^{\alpha x} + Be^{-\alpha x}$ in the region x less than equal to a plus b greater than a . I have $\psi(x)$ equals $Ce^{i\beta x} + De^{-i\beta x}$ and at x equals a plus b plus slightly to the right of a plus b , I have $\psi(a+b)^+$ is equal to $e^{ik(a+b)}\psi(0)$ and this will be equal to $e^{ik(a+b)}(A+B)$ and $\psi(0)$ from the first equation is nothing but $A+B$ and I also have $\psi'(a+b)^+$ is equal to $e^{ik(a+b)}\psi'(0)$ and this will be $e^{ik(a+b)}(\alpha A - \alpha B)$.

So, 2 equations that I get from here are that $\psi(a+b)^+$ is equal to $e^{ik(a+b)}(A+B)$ equation 1 and then I have $\psi'(a+b)^+$ is equal to $e^{ik(a+b)}(\alpha A - \alpha B)$ equation 2. On the other hand $\psi(a+b)^+$ should be same as $\psi(a+b)$ and that is calculated from this equation here and therefore $\psi(a+b)^+$ is also equal to $Ce^{i\beta(a+b)} + De^{-i\beta(a+b)}$.

And similarly $\psi'(a+b)^+$ should also be equal to $\psi'(a+b)$ calculate from the left hand side and therefore I am going to have $i\beta(Ce^{i\beta(a+b)} - De^{-i\beta(a+b)})$. So, these are 2 equations I can remove the middle part now, so let me do that I can just remove this part and these are the 2

equations relating C and D to A and B. I need 2 more equations on those 2 equations come from continuity at $x = a$.

(Refer Slide Time: 13:49)

Continuity of wavefunction at $x = a$

gives

$Ae^{\alpha a} + Be^{-\alpha a} = Ce^{i\beta a} + De^{-i\beta a}$ — (I)

$\alpha (Ae^{\alpha a} - Be^{-\alpha a}) = i\beta (Ce^{i\beta a} - De^{-i\beta a})$ — (II)

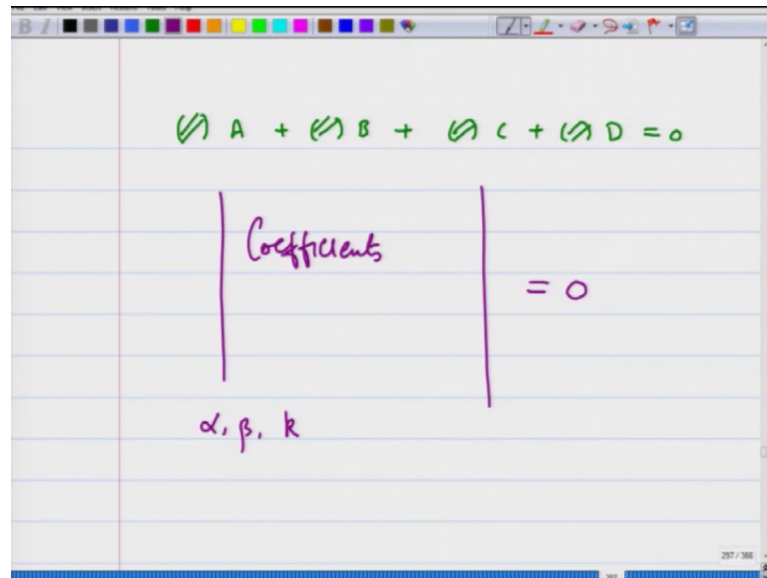

$(A+B)e^{ik(a+b)} = Ce^{i\beta(a+b)} + De^{i\beta(a+b)}$ — (III)

$\alpha (A-B)e^{ik(a+b)} = i\beta (Ce^{i\beta(a+b)} - De^{-i\beta(a+b)})$ — (IV)

So, continuity of wave function at $x = a$ gives remember these are the regions I know wave function here I know wave function here. So, I am going to have $Ae^{\alpha a} + Be^{-\alpha a}$ is equal to $Ce^{i\beta a} + De^{-i\beta a}$ that is my equation number 3 and the continuity of the derivative of the wave function gives $\alpha (Ae^{\alpha a} - Be^{-\alpha a})$ is equal to $i\beta (Ce^{i\beta a} - De^{-i\beta a})$. This is my equation number 4.

So, I have gotten 4 equations. I have written number 3 and 4 here number, 1 and 2 on the previous slide, but let me write them again here for completeness. So, number 1 and 2 were $(A+B)e^{ik(a+b)} = Ce^{i\beta(a+b)} + De^{i\beta(a+b)}$ and this was equation number 1 and the second equation was $\alpha (A-B)e^{ik(a+b)} = i\beta (Ce^{i\beta(a+b)} - De^{-i\beta(a+b)})$ this is equation number 2.

(Refer Slide Time: 16:12)

The image shows a digital whiteboard with a toolbar at the top. The first line contains the equation $A + B + C + D = 0$ written in green. The second line shows a determinant symbol consisting of two vertical purple lines, with the word "Coefficients" written in purple between them. To the right of the determinant is an equals sign followed by a zero. Below the determinant, the variables α, β, k are written in purple.

I have got 4 unknowns, 4 equations and I can put them in this form. Some coefficient A plus some coefficient B plus some coefficient C plus some coefficient D is equal to 0 like this there are 4 equations. So, I have these 4 equations and all of them go to 0 if A and B and C and D have to be nonzero, non trivial solution I should have this determinant of the coefficients is equal to 0 and that gives a relationship between alpha beta and k and through that I remember alpha and beta are related to energy and V_0 , so through this I get e as E function of k .

I will now simplify all this part you should work out and I will give this as an assignment. I will simplify all this for the purposes of illustration here and reduce the number of variables due to by taking a very special form of Kronig- Penney model and in that what I will do is I will shrink the barriers to zero size and take these functions as delta functions.

(Refer Slide Time: 17:30)

The image shows a whiteboard with handwritten mathematical content. At the top, a diagram illustrates a potential well with two vertical barriers at $x=0$ and $x=b$, with a double-headed arrow between them labeled b . Below the diagram, the potential function is given as $V(x) = V_0 \sum_s \delta(x-sb)$. The Schrödinger equation is written as $-\frac{\hbar^2}{2m} \psi'' + V\psi = E\psi$ for $0 \leq x \leq b$. This is then simplified to $\psi'' + \frac{2mE}{\hbar^2} \psi = 0$. Finally, the general solution is boxed as $\psi(x) = A e^{i\beta x} + B e^{-i\beta x}$.

So, all these potentials $V(x)$, so I will take the potential $V(x)$ to be of the form $V_0 \sum_s \delta(x-sb)$, where b is the distance between these barriers. So, I have shrunk the width a of the potential barrier to be 0 and increase the height to V_0 . So, this is the potential which is periodic potential and here you will see that the number of variables are only 2.

So, again let me take the point at the first barrier to be $x=0$ and the other point becomes $x=b$. If I take the solution of the Schrodinger equation $E\psi$ for x between 0 and b potential is 0 and therefore I get $\psi'' + \frac{2mE}{\hbar^2} \psi = 0$ and I get $\psi(x) = A e^{i\beta x} + B e^{-i\beta x}$. That is the solution for the region between 0 and b .

(Refer Slide Time: 18:58)

The image shows a digital whiteboard with handwritten notes. At the top, there is a diagram of a potential barrier. A horizontal line represents the potential, with two vertical lines representing barriers at $x=0$ and $x=b$. A green arrow above the line indicates a wave moving from left to right. The region between $x=0$ and $x=b$ is labeled with a question mark. Below the diagram, the wave function is given as $\psi = A e^{i\beta x} + B e^{-i\beta x}$. At $x=0$, the wave function is $\psi(x=0) = A + B$ and its derivative is $\psi'(x=0) = i\beta(A - B)$. A bracket groups these two equations, with $\beta = \sqrt{\frac{2mE}{\hbar^2}}$ written to the right. At $x=b^+$, the wave function is $\psi(x=b^+) = e^{i\beta b} \psi(0) = e^{i\beta b} (A + B)$. At the bottom, the potential is given as $V = V_0 \delta(x-b)$.

So, let me make this potential again. In this region I have got the solution psi equals A e raise to i beta x plus B e raise to minus i beta x. Point at the left barrier is x equals 0 and point on the right barrier x equals b. So, psi at x equals 0 is A plus B psi prime at x equals 0 is i beta A minus B. In both these beta is equal to square root of 2 m E over h cross square.

Notice that I have naught used Bloch's theorem so far which I am going to do now. Let us look at the point x equals b plus. That means, I am looking at a point here slightly to the right of x equals b and this point is displaced from x equals 0 plus y b. So, I can write that wave function psi at x equal's b plus by Bloch's theorem is going to be e raise to i k b psi at 0. So, this is going to be e raise to i k b a plus b. Now psi prime here is slightly settle.

Because I have a delta function between b plus and b minus. So, the potential at point b is delta V 0 delta x minus b and this gives a slight subtlety 2 the derivative of the wave function is not continuous and let us check that.

(Refer Slide Time: 20:58)

The image shows a whiteboard with the following handwritten content:

$$-\frac{\hbar^2}{2m} \psi''(x) + V_0 \delta(x-b) \psi = E \psi$$

Integrating from $b-\epsilon$ to $b+\epsilon$ and taking the limit $\epsilon \rightarrow 0$:

$$\lim_{\epsilon \rightarrow 0} \int_{b-\epsilon}^{b+\epsilon} \Rightarrow -\frac{\hbar^2}{2m} (\psi'(b^+) - \psi'(b^-)) + V_0 \psi(b) = \int_{b-\epsilon}^{b+\epsilon} E \psi dx$$

Since ψ is continuous and $E \psi$ is finite, the right-hand side goes to zero. This leads to the boxed equation:

$$\psi'(b^+) - \psi'(b^-) = \frac{2m V_0}{\hbar^2} \psi(b)$$

Equation (I) for the wave function continuity:

$$\psi(b^+) = (A+B) e^{ikb} = A e^{i\beta b} + B e^{-i\beta b} \quad \text{--- (I)}$$

Equation (II) for the derivative jump:

$$i\beta(A-B) e^{ikb} - i\beta(A e^{i\beta b} - B e^{-i\beta b}) = \frac{2m V_0}{\hbar^2} (A+B) e^{ikb} \quad \text{--- (II)}$$

So, I have minus h cross square over 2 m, psi double prime x plus V 0 delta x minus b psi equals E psi. Let us integrate this equation from b minus epsilon to b plus epsilon where epsilon is tending to 0. When I integrate this I am going to get minus h cross square over 2 m psi prime at b plus minus psi prime at b minus plus V 0 psi at b. Keep in mind that the wave function psi is continuous, so at b plus b minus is the same is equal to epsilon is finite. So, when I integrate from b minus epsilon to b plus epsilon E psi E psi being E and psi both being finite this follows 0 and therefore I get psi prime b plus minus psi prime b minus is equal to 2 m V 0 over h cross square psi at b.

That is the condition on the derivative of the wave function. So, what we have found is 2 equations that relate the wave function across b and we have 2 unknowns a capital A and capital B, so that is all that is needed to solve the equation right. So, let us write this so I have the equation that A plus B e raise to i k b is the wave function at psi b plus and it should be continuous. Therefore this whole thing should be equal to the wave function coming from the left and that is A e raise to i beta b plus B e raise to minus i beta b. That is my equation number 1.

And equation number 2 gives the difference between the derivatives and therefore I get psi prime at b plus 1 is nothing but i beta A minus B and if I multiply by this by e raise to i k b this gives me psi prime at b plus 1 by Bloch's theorem minus psi prime at b minus and that will be i beta A e raise to i beta b minus B e raise to minus i beta b and this

should be equal to $2 m V_0$ over h cross square psi at b , which I can write either as $A \cos k b + B \sin k b$ or $A e^{i k b} + B e^{-i k b}$. I choose the former and this becomes $A \cos k b + B \sin k b$. This is my equation number 2. I have 2 equations, 2 coefficients A and B if I want a and b to be non trivial the coefficients of A and B must form a determinant that is 0.

(Refer Slide Time: 24:48)

Rewrite these equations

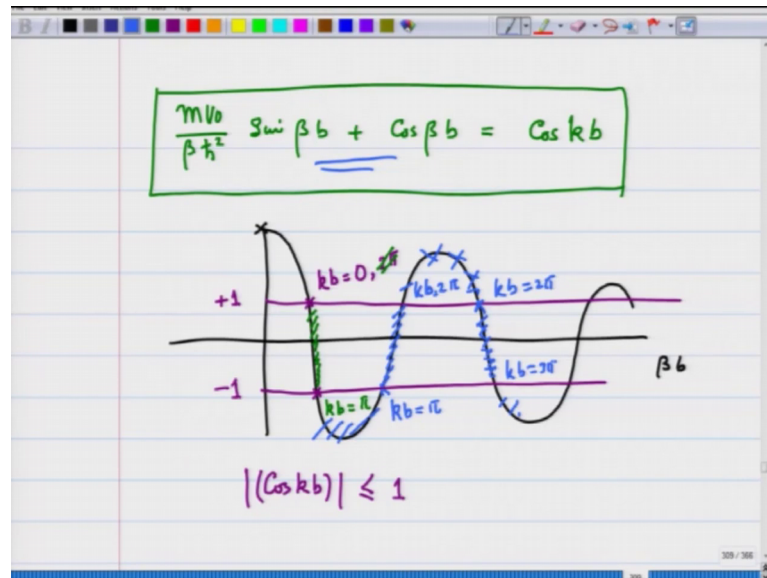

$$\left. \begin{aligned} (\cos) A + (\sin) B &= 0 \\ (\sin) A + (\cos) B &= 0 \end{aligned} \right\}$$

$$\begin{vmatrix} \cos & \sin \\ \sin & \cos \end{vmatrix} = 0$$

The image shows a digital whiteboard with a toolbar at the top. The text 'Rewrite these equations' is written in black. Below it, two equations are written: $(\cos) A + (\sin) B = 0$ and $(\sin) A + (\cos) B = 0$, with a large right-facing curly bracket to their right. Below the equations, a determinant is written in green: $\begin{vmatrix} \cos & \sin \\ \sin & \cos \end{vmatrix} = 0$.

So, I do that so, I rewrite these equations as coefficient A plus some coefficient B is equal to 0 another coefficient A plus another coefficient B is equal to . These are my 2 equations which I have rewritten and then I write the determinant of these coefficients and make it equal to 0 and that leads to the equation and I am going to write the equation directly rest I will leave for you to work out and these equations when they are coefficients are made 0 they gave me $m V_0$ over h cross square \sin of βb plus \cos of βb is equal to \cos of $k b$.

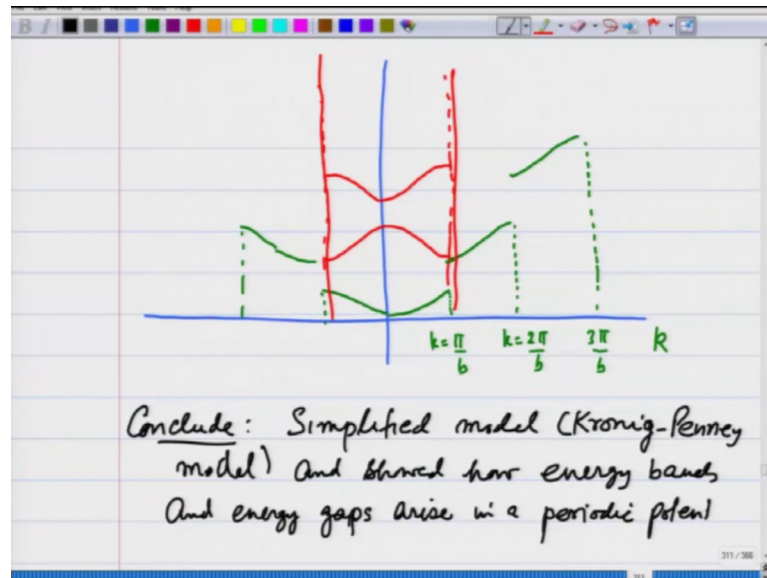

(Refer Slide Time: 25:57)

I will leave that working out to you. It is quite easy the only difference between the general Kronig- Penney that I obtained earlier and this is that right now my determinant becomes simplest 2 by 2 determinants and this equation I will now show you leads to band gaps. If I plot the left hand side, as a function of beta b, it starts at a high value and goes like this the value becomes smaller and smaller and this value out here is greater than 1. If I plot the limits plus one and minus one there like this, this is minus 1 this is plus 1. Now according to the equation written, the maximum value that this function can take is plus 1 and the minimum value it can take is minus 1 because cosine k b modulus is less than equal to 1.

So, when cosine k b is plus 1 I have k b equals either 0 or 2 pi and then you get energies continuously from here up to minus 1. So, k b equals pi so I will take k b equals 0 here. So 0 to k b equals pi you get continuous energy and at k b equals pi you see the energies where the value of the function on the left hand side here is greater than 1. This equation does not have a solution. So, at k b equals pi this point again is k b equals pi there is a gap in the energy, there is a gap in beta or beta times b that is there is no solution, this is the energy gap and again from k b equals pi to k b equals 2 pi, we have continuous energies. But as soon as you hit k b equals 2 pi again you go to a region where the equation is not satisfied and again k b equals 2 pi, so there is a gap and then again you have allowed solutions and then again k b equals 3 pi you have a gap.

(Refer Slide Time: 28:52)

So, the situation is that if I were to plot the energy versus k you have up to $k b$ equals π some continuous energy this is k equals π over b and then there is a gap, then again I have continuous energy up to k equals 2π by b and again there is a gap. Then I have continuous energy again up to 3π by b and then there is a gap. Same thing on the other side because the symmetry and then I can translate all these curves to the first Brillouin zone and make my second band like this and third band like this and so on, so in this zone I have this band structure.

So, what I have shown you through the simple Kronig- Penney model which was further simplified by taking the delta function barrier that by applying Bloch's theorem, we got energies which are continuous in the range 0 to π by b for k and then at $k b$ equals π that is k times the periodicity length at each of these there is an energy gap that exists because the equation cannot be satisfied.

So, to conclude this lecture, we have taken a simplified model called Kronig- Penney model and showed how energy bands and energy gaps arise in a periodic potential.

Thank you.
