Lecture - 20
Waves in guided structures and modes
(contd.)

We will be discussing the simplest type of optical waveguide namely the dielectric interface planar slab waveguide.

(Refer Slide Time: 00:27)

(Refer Slide Time: 00:28)

Contents

- ✓ Symmetric Slab waveguides, TE –modes , eigenvalue equations, symmetric and antisymmetric modes
- ✓ V number, number of modes , field distributions, single-mode operation, cut-off properties, symmetric RI profiles

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri
Physics

And, in the discussion we will look at the symmetric nature of the refractive index profile and the TE modes TM modes of the waveguide, then eigenvalue equation symmetric and anti symmetric modes which we will see is a consequence of the symmetric refractive index profile. Then we will define a quantity which is very relevant and very important is used for defining almost all kinds of optical waveguides, then we will look at the a number of modes supported by an optical waveguide of this kind then the field distribution across the waveguide.

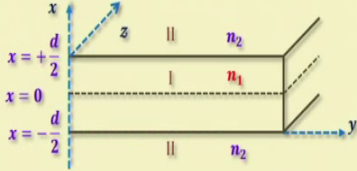

Then there will be another important point that is the mode field that is the single mode operation of the waveguide, this particular property is very useful extremely useful in almost all applications then we will look at the cutoff properties of the various modes which are supported by the waveguide. Then this consequence of symmetric refractive index profile which will give rise to only symmetric and anti symmetric modes. So, with these points in mind we will discuss the planer dielectric slab waveguide.

(Refer Slide Time: 02:03)

Planar dielectric waveguide

Symmetric SLAB Structure

Infinite along y – direction
 Dielectric-dielectric interfaces
 Slab thickness = d and RI = n_1
 RI of both outside media = n_2

Wave equation satisfied by waves in each homogeneous layer of the waveguide

$$\frac{d^2 E_y}{dx^2} + [k_0^2 n^2(x) - \beta^2] E_y = 0; \quad \text{where } n^2(x) = n_1^2 : \pm \frac{d}{2} > |x|$$

$$n^2(x) = n_2^2 : \text{elsewhere}$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri | Physics

So, this is one the simple most structure where you have the refractive index n_1 which is sandwiched between the 2 same refractive index layers that is of refractive index n_2 , these are the 2 interfaces so that there are 2 regions region 2 and region 1. Because, of the nature of the waveguide we assume that this y direction that is along this direction the waveguide is infinite and there is a refractive index profile variation only along this x direction.

But this variation is a constant it gives rise to constant homogeneous refractive indices, so there is a change in the refractive index across the interface. So, we will look at this property we assume that the thickness of the slab is d , so that and we set our coordinate system across this middle axial line such that the upper interface falls at x equal to $d/2$ and the lower interface at x equal to $-d/2$. So, these are the notations in parameters that will use in the determination of the waveguide modes and eigenvalue equations.

So, in this case the wave equation that is satisfied by the waves which will be propagating through this structure, in each of the homogeneous layer of the waveguide will be given by this homogenous equation. That is we consider the TE mode therefore this E_y is the electric field component which is non managing and H_x H_z will also associate with this E_y . So, for region 1 that is within this layer which will got the core and the other 2 layers surrounding this core will be called the cladding is the

conventional nomenclature. Where so n^2 of x the refractive index varies along this direction, which is constant as long as this mode of x is less than plus minus $\frac{d}{2}$. So, I define this layer which will have a refractive index n_1 and otherwise everywhere this is equal to n_2 square. So, the cladding refractive index is n_2 whereas the core refractive index is n_1 .

(Refer Slide Time: 04:58)

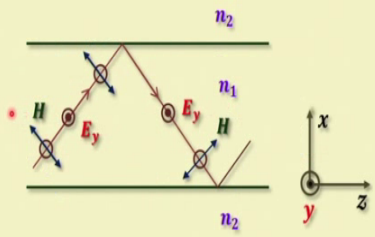

Symmetric dielectric Slab: TE- mode

TE- modes

\vec{E} fields are now parallel to interface planes, i.e., $\vec{E} = \hat{y}E_y$

$$\frac{\partial^2 E_y}{\partial x^2} + (k_0^2 n^2(x) - \beta^2) E_y = 0$$

where $n^2(x) = n_1^2 : \pm \frac{d}{2} > |x|$
 $n^2(x) = n_2^2 : \text{elsewhere}$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri | Physics

So, for TE modes once again we will look at this configuration we have E_y field which are parallel to the interface planes E_y and H field magnetic field components will lie in the $x-z$ plane. So, it will give rise to 2 components and this E_y comes through this equation that is this homogenous equation that is $\nabla^2 E_y$ by ∂x^2 plus this quantity into E_y equal to 0. So, this the mathematical representation for the refractive index profile and the wave equation for this structure as long as we are concerned with the TE modes.

(Refer Slide Time: 05:47)

** For region I : $\frac{d^2 E_y}{dx^2} + [k_0^2 n_1^2 - \beta^2] E_y = 0$: *core*

For region II : $\frac{d^2 E_y}{dx^2} - [\beta^2 - k_0^2 n_2^2] E_y = 0$: *cladding*

Define mode parameters: $\left. \begin{aligned} \kappa^2 &= k_0^2 n_1^2 - \beta^2 \\ \gamma^2 &= \beta^2 - k_0^2 n_2^2 \end{aligned} \right\} \Rightarrow \text{These are the } x\text{-components of } \vec{k} \text{ in the core and cladding respectively}$

With these definitions: $\frac{d^2 E_y}{dx^2} + \kappa^2 E_y = 0$ (1)

$\frac{d^2 E_y}{dx^2} - \gamma^2 E_y = 0$ (2)

The diagram shows a waveguide cross-section with a core of refractive index n_1 and cladding of refractive index n_2 . A propagation vector \vec{k} is shown in the core, with its x-component κ and z-component β . In the cladding, the x-component is γ and the z-component is β .

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri | Physics

For the region one that is the one this region that is this region within the core we have this equation, because this n square of x now assumes a constant value that is n 1 square. So, for the core we have this equation and for region 2 that is for the cladding there are 2 such regions, so we have this equation and we write this slightly in a modified way we take this minus out and put it in this form. The intension is very simple because beta we will see that beta should lie somewhere between $k_0 n_1$ and $k_0 n_2$. So, to make it positive beta square minus $k_0^2 n_1^2$ square, this quantity will be positive which is the transverse component of the propagation constant in the cladding and we call this quantity as gamma square so I write this equation for cladding like this.

Then we define the mode parameters this we have seen these are the x components of the k vector in the core and cladding, so kappa square is written as $k_0^2 n_1^2$ minus beta square beta is the z component of the propagation vector beta is z and kappa will have a x component and along y direction we have assume that the waveguide is infinite. So, we get rid of the y component of this k vector, so the k x and k z these 2 constitute k k x within the core we have called kappa and outside this k within the with the within the cladding we call this is gamma and because n_1 is more than beta we write in this way whereas beta is more than n_2 , so we write in this way for modes to be supported.

So, we will look at this condition later with these definitions then we can write this equation that $\frac{d^2 E_y}{dx^2} + \kappa^2 E_y = 0$ for the first

equation and for the second equation we can write this del square E y by del x square minus gamma square E y equal to 0. So, these are the 2 equations to wave equations for E y governing the propagation of the electric field in the structure for the core and the cladding.

(Refer Slide Time: 08:29)

Solutions: TE- mode

Solutions to (1) and (2) are as : $E_y(x) = A' e^{ikx} + B' e^{-ikx}$ for (1)

$E_y(x) = C e^{-\gamma x} + D e^{\gamma x}$ for (2)

We may write (1) in this form : $E_y(x) = A \cos \kappa x + B \sin \kappa x$

Also $C = D$ as the waveguide is x -symmetric in RI profile

We write (2) for both regions : $E_y(x) = C e^{-\gamma x}$ for $x > \frac{d}{2}$

$E_y(x) = D e^{+\gamma x}$ for $x < -\frac{d}{2}$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri | Physics

So, so the solutions to 1 and 2 the solution to this equation is very well known very well known and it appears very frequently in physics, this equation will give you an isolated solution for E y which can be written as A e to the A dash e to the power of i k x plus B dash e to the power of minus i k x. I used dash because we can we can simplify this using some different constants and for the cladding region. This equation will give you the solution that is which will be exponentially decaying solution because, you have a minus here this equation is also very well known in physics.

So, these 2 equations put together will give me the complete field solutions in the core and cladding of the symmetric refractive index dielectric waveguide. So, we may write equation 1 that is what I told just now that we can write in the sine cosine form, so this A e to the power of i k x B dash e to the power of minus i k x can be simply written in this form A cosine kappa x plus B sine kappa x. Now because of the symmetric nature of the waveguide because this side and this side they are identical, so both of them will be treated with the same constant. So, therefore C and D are same as long as the waveguide has a symmetric refractive index profile.

The variation of the field along with this direction and along this direction will associate the same constant that is what the idea is and in that case this quantity the first part will represent an exponentially decaying wave when x is positive. But this second part will be representing an exponentially decaying wave when x is negative and because C e is equal to D e. So, this will represent only the upper part of the upper half of the interface. So, the wave which will be travelling across this layer will be e to the power of minus gamma x, but the wave which will be travelling across this will be e to the power of plus gamma x because x is negative here.

Therefore with this notation and convention we write this equation E y for d x greater than d by 2 that is for upper half C e to the power gamma x and E y for the for the layer below the lower interface will be represented whenever the C and D they are identical in the case of a symmetric structure.

(Refer Slide Time: 11:19)

Now, at $x = +\frac{d}{2}$: upper interface

$$E_y \left(x = +\frac{d}{2} \right)_{\text{region I}} = E_y \left(x = +\frac{d}{2} \right)_{\text{region II}} \Rightarrow A \cos \frac{\kappa d}{2} + B \sin \frac{\kappa d}{2} = C e^{-\frac{d}{2}\gamma}$$

$$\frac{\partial E_y}{\partial x} \left(x = +\frac{d}{2} \right)_{\text{region I}} = \frac{\partial E_y}{\partial x} \left(x = +\frac{d}{2} \right)_{\text{region II}} \Rightarrow -A \kappa \sin \frac{\kappa d}{2} + B \kappa \cos \frac{\kappa d}{2} = -\gamma C e^{-\frac{d}{2}\gamma}$$

Multiplying (1) by γ and add : $\tan \frac{\kappa d}{2} = \frac{A\gamma + B\kappa}{A\kappa - B\gamma}$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri | Physics

Now, we will use the boundary conditions for the continuity of the tangential component of the fields, so at x equal to plus d by 2 that is at the upper interface. At upper interface we can use this E y must be continuous across the interface layer and that gives you a cosine I just have to plug in that x equal to plus d by 2 on either side of this of this equation on either side of this equation this equation and this equation in these 2 equations we will use x equal to plus d by 2.

So, that gives you this condition and if I assume the continuity of the derivative of the field that is $\frac{\partial E_y}{\partial x}$ across the interface, which is also a continuity condition we end up with this equation. Now, that if we just combine these 2 if we just combine these 2 equations multiplying 1 by γ you just have to multiply one by γ then this quantity and this quantity will be same. But with a difference of minus sign and if you then add then you will add up with this condition $\tan \kappa d$ by 2 equal to $A \gamma$ plus $B \kappa$ by $A \kappa$ minus $B \gamma$ is a very very well known equation. So, I have used the continuity condition for the upper interface and that is for the field continuity and the derivative of the field continuity I have not used the lower interface, which will also give me the same boundary same equation same relation.

(Refer Slide Time: 13:13)

Now, at $x = -\frac{d}{2}$: lower interface

$$E_y \left(x = -\frac{d}{2} \right) \Big|_{\text{region II}} = E_y \left(x = -\frac{d}{2} \right) \Big|_{\text{region III}} \Rightarrow A \cos \frac{\kappa d}{2} - B \sin \frac{\kappa d}{2} = D e^{-\frac{d}{2}\gamma}$$

$$\frac{\partial E_y}{\partial x} \left(x = -\frac{d}{2} \right) \Big|_{\text{region II}} = \frac{\partial E_y}{\partial x} \left(x = -\frac{d}{2} \right) \Big|_{\text{region III}} \Rightarrow A \kappa \sin \frac{\kappa d}{2} + B \kappa \cos \frac{\kappa d}{2} = \gamma D e^{-\frac{d}{2}\gamma}$$

Multiplying (1) by γ and equate: $\tan \frac{\kappa d}{2} = \frac{A\gamma - B\kappa}{A\kappa + B\gamma}$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri
Physics

So, to see that at x equal to minus d by 2 at the lower interface that is x equal to minus d by 2, if I plug in this relation then I will end up with this equation this relation and also from this continuity of the derivative of the field will give me this condition and preceding in the same way that is multiplying 1 by γ and then if we equate these 2 because in this case this right hand side will be equal and from there we can we can get a relation. So, there is a slight difference between this $A \gamma$ plus $B \kappa$, whereas in this case $A \gamma$ minus $B \kappa$ and in the denominator you have plus; whereas, in the earlier case it was minus but both of them will represent $\tan \kappa d$ by κd by 2.

(Refer Slide Time: 14:03)

Since LHS's of both the conditions are the same it follows that

$$\frac{A\gamma + B\kappa}{A\kappa - B\gamma} = \frac{A\gamma - B\kappa}{A\kappa + B\gamma}$$

This on simplification reduces to $2AB(\kappa^2 + \gamma^2) = 0$

This tells you 2 possibilities

- (1) $\gamma^2 = -\kappa^2$; all layers are of same RI
- (2) $AB = 0$; saying that $A = 0$ or $B = 0$

IIT KHARAGPUR

NPTEL ONLINE
CERTIFICATION COURSES

Partha RoyChaudhuri
Physics

So, therefore these 2 must be equal to represent the same waveguide and same parameter same structure this eigenvalue equation must be holding good. Now if you simplify this will give you a condition that if you multiply this into this and this into cross multiplication will end up with this simplified condition twice A into B kappa square plus gamma square. It is a very simple algebraic steps to execute, then we will end up with this equation, now once we have this equation in hand it tells you 2 possibilities.

First one is that that either kappa square plus gamma square must be equal to 0, in that case gamma square equal to minus kappa square. But that means that means n_1 and n_2 they are equal, if you look at the definition of kappa and gamma n_1 and n_2 because beta will cancel $k_0 n_1$ square will be equal to $k_0 n_2$ square. So that means n_1 is equal to n_2 that means all layers are the same there is no waveguide there is no interface so that is a trivial condition. So, we will not continue with this condition we will look at this $A B$ equal to 0 the other possibility, so that means either A equal to 0 or B equal to 0.

(Refer Slide Time: 15:23)

(1) $\gamma^2 = -\kappa^2$;
 $\kappa^2 = k_0^2 n_1^2 - \beta^2$ and $\gamma^2 = \beta^2 - k_0^2 n_2^2$
 $n_1^2 = n_2^2 \Rightarrow n_1 = n_2 \Rightarrow$ no interface and no waveguiding \Rightarrow trivial

(2) $AB = 0$; $A = 0$ or $B = 0$

We start from any of the condition

say, $B = 0$; then $\tan \frac{\kappa d}{2} = \frac{\gamma}{\kappa}$

and for, $A = 0$; then $\tan \frac{\kappa d}{2} = -\frac{\kappa}{\gamma}$

The slide also features logos for IIT KHARAGPUR, NPTEL ONLINE CERTIFICATION COURSES, and the presenter's name, Partha RoyChaudhuri, Physics.

So, these 2 conditions will lead to the other possibilities, so this one I have already explained that that kappa square equal to minus gamma square will give you no interface and this is a trivial condition for this. Let us suppose we start with the condition B equal to 0, then from this equation from this equation if I put B equal to 0 B equal to 0 then you get that gamma by kappa and this gamma by kappa.

If I put this equation then the tangent value of this lets go to this, so tan k d by 2 will become equal to B equal to 0 you have put so you get gamma by kappa, so tan k kappa d by 2 will be equal to gamma by kappa. So that is the equation which comes out of the condition that B equal to 0. So, I put B equal to 0 I get this condition and in the similar way if I put A equal to 0 I will get this condition. In that case I will put when you put A equal to 0 you get kappa by gamma the reciprocal of the earlier case that is an with an negative sign right, so you get 2 conditions for B equal to 0 and A equal to 0.

(Refer Slide Time: 16:42)

Eigenvalue equations: TE- mode

For $B = 0$; $E_y(x) = A \cos \kappa x$ $|x| < \frac{d}{2}$ Symmetric field distribution

$E_y(x) = C e^{-\gamma|x|}$ $|x| > \frac{d}{2}$

Using this condition in $\frac{A\gamma + B\kappa}{A\kappa - B\gamma} = \frac{A\gamma - B\kappa}{A\kappa + B\gamma}$

Obtain the eigenvalue equation

$$\tan \frac{\kappa d}{2} = \frac{\gamma}{\kappa} \Rightarrow \frac{\kappa d}{2} \tan \frac{\kappa d}{2} = \frac{\gamma d}{2}$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri
Physics

Now, eigenvalue equation so this defines the eigenvalue equations this, if I put this in the solution of E_y for the core that is mode x less than d by 2 I get this field solution which tells you because it is a cosine function, so the fields are symmetric. So, this gives you the symmetric field distribution all fields will be symmetric and this is a anyway a evanescent field evanescently decaying field at the outer at the at the cladding region starting from the interface. So, using this using this condition in this equation then we get the eigenvalue equation using this condition.

We get the eigenvalue equation as this $\tan \kappa d$ by $2 \tan$ because in that case we have to multiply d by 2 and d by 2 numerator and denominator if you bring it to the left hand side you get κd by $2 \tan \kappa d$ by 2 equal to γd by 2 . So, this is the eigenvalue equation corresponding to the symmetric field distribution which corresponds to the condition that B equal to 0 and let us define this V number which is a very important parameter for optical waveguides, V defined as k_0 half of the thickness this is different in different text books. This is half of the half of the thickness and this is the numerical aperture and n_1 square minus n_2 square, so the core cladding refractive index square difference.

(Refer Slide Time: 18:14)

Define V number : $V = k_0 \frac{d}{2} \sqrt{n_1^2 - n_2^2}$

Such that : $V^2 = \frac{d^2}{4} (k_0^2 n_1^2 - k_0^2 n_2^2) = \frac{d^2 \kappa^2}{4} + \frac{d^2 \gamma^2}{4}$

$\Rightarrow V^2 = \left(\frac{\kappa d}{2}\right)^2 + \left(\frac{\gamma d}{2}\right)^2$

$V^2 = x^2 + y^2$ ——— (A)

Eigenvalue relation : $\frac{\kappa d}{2} \tan \frac{\kappa d}{2} = \frac{\gamma d}{2}$

$\Rightarrow y = x \tan x$ ——— (B)

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, V square is equal to this quantity and you can see that the that you can write this equation as $k d$ square by 4 and γd square by 4 because, if you add one if you subtract 1 beta square and then add 1 beta square this quantity will correspond to correspond to kappa and the other quantity will correspond to gamma. So, that is why I have written this V square is equal to this, so V square can be put into this form and you can see that V square equal to x square plus y square if you call this quantity equal to x and if you call this quantity equal to y .

So, you can write this equation which is the equation of a circle of radius V and these are the equations which are the outcome of the of the eigenvalue equation. Now, now I so this is the consequence of the definition of V number which appears in terms of the kappa and gamma and this is the eigenvalue equation.

(Refer Slide Time: 19:18)

In the same way.....

For $A = 0$; $E_y(x) = B \sin \kappa x$ $|x| < \frac{d}{2}$ Antisymmetric field distribution

$E_y(x) = \frac{x}{|x|} C e^{-\gamma|x|}$ $|x| > \frac{d}{2}$ Antisymmetric modes

Using this condition in $\frac{A\gamma + B\kappa}{A\kappa - B\gamma} = \frac{A\gamma - B\kappa}{A\kappa + B\gamma}$

Obtain the eigenvalue equation

$$\tan \frac{\kappa d}{2} = -\frac{\kappa}{\gamma} \Rightarrow -\frac{\kappa d}{2} \cot \frac{\kappa d}{2} = \frac{\gamma d}{2}$$

Now to look for the solution of the modes [FL] in the same way in the same way A equal to 0 e to the E y of x this will be the field solution and that corresponds to anti symmetric modes and these the evanescently decaying field will be the same. Using this condition I again from here can arrive at this condition which will be the eigenvalue equation for the anti symmetric modes. We can actually put 2 of them together in 1 compact eigenvalue equation which will represent both symmetric and anti symmetric modes.

(Refer Slide Time: 19:58)

Again using V number :

$$\Rightarrow V^2 = \left(\frac{\kappa d}{2}\right)^2 + \left(\frac{\gamma d}{2}\right)^2$$

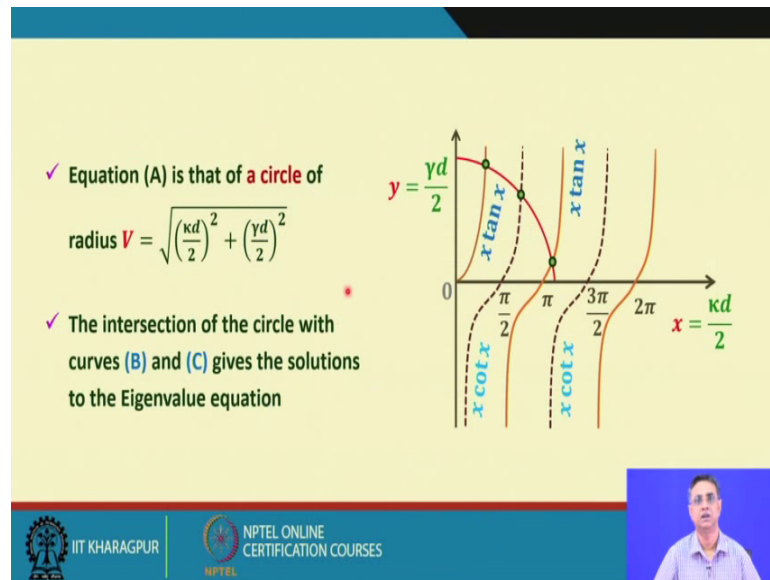

$$\Rightarrow V^2 = x^2 + y^2 \quad \text{--- (A)}$$

Eigenvalue equation : $-\frac{\kappa d}{2} \cot \frac{\kappa d}{2} = \frac{\gamma d}{2}$

$$\Rightarrow y = -x \cot x \quad \text{--- (C)}$$

Now, again using V number for the anti symmetric modes we can write this equation which is the same and for the eigenvalue equation now this time it becomes y equal to minus x cot of x cotangent of x . So, we have 2 eigenvalue equations and one equation of a circle.

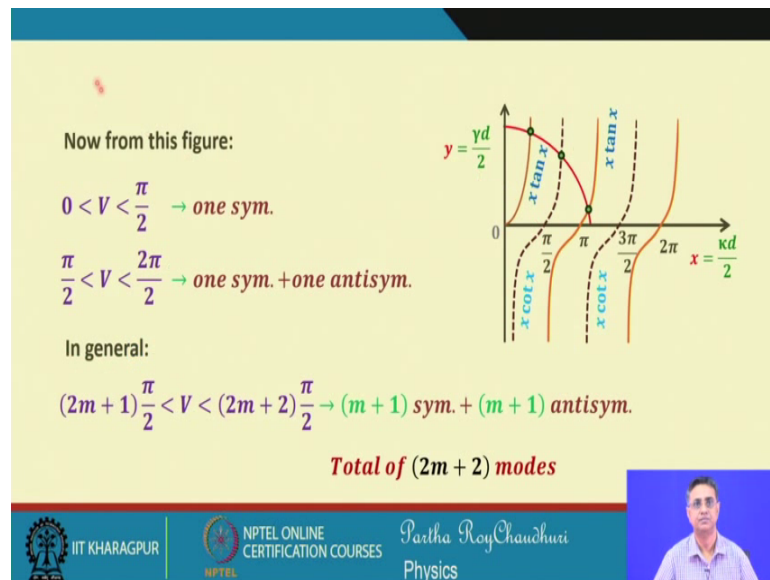

(Refer Slide Time: 20:15)

So, we plot them we plot them because we are looking for the solution of the modes, so this is your $x \tan x$ this is your $x \cotangent x$ alternatively they are appearing and now I draw a circle of radius V which is equal to this which is equal to this. So, at this point it will be γd by 2 and at this point it will be κd by 2. So, this radius the point of intersection of the circle with the curves B and C gives the solution to the eigenvalue equation.

So, you can see that this there will be one solution here for the value of V which is less than π by 2, here this will be less than π again it is close to π so on and so forth for this value of V and if you increase the value of V we will get we will get more number of solutions. So, it is the V that is going to decide V number we going to decide how many modes will be supported in the structure.

(Refer Slide Time: 21:19)

Now from this figure you can see when the value of V is less than $\pi/2$ is less than $\pi/2$ because this line less than $\pi/2$. So, you have only one symmetric mode, but if the value of V is between $\pi/2$ and π then you have this point of course, this encloses this point. So, you have one symmetric mode the value which lies between $\pi/2$ and π somewhere here then you can have one symmetric one symmetric mode and one anti symmetric mode. So, there will be 2 modes and in this way if you proceed for the values of V which lies between twice m plus $\pi/2$ and twice m plus π that is within a spread of $\pi/2$ between these 2 positions.

Then you will have m plus one symmetric mode and m plus one anti symmetric mode modes. So, this is simply just by induction of these 2 initial facts we can we can arrive at the conclusion that the total number of modes will be supported that is equal to twice m plus 2, provided that the value of V lies between this is twice m plus 2. So, this is the total number of modes which will be supported, we will see how the modes look like now equation A is so total number of modes we have supported.

(Refer Slide Time: 22:50)

Total no. of modes

Thus if $(2m + 1)\frac{\pi}{2} < V < (2m + 2)\frac{\pi}{2} \rightarrow (m + 1) \text{ sym.} + (m + 1) \text{ antisym.}$

$$V < (2m + 2)\frac{\pi}{2} \Rightarrow (2m + 2) > \frac{2V}{\pi} \Rightarrow N > \frac{2V}{\pi} \text{ Total of } (2m + 2) \text{ modes}$$

And if: $2m\frac{\pi}{2} < V < (2m + 1)\frac{\pi}{2} \rightarrow (m + 1) \text{ sym.} + m \text{ antisym.}$

$$V < (2m + 1)\frac{\pi}{2} \Rightarrow (2m + 1) > \frac{2V}{\pi} \Rightarrow N > \frac{2V}{\pi} \text{ Total of } (2m + 1) \text{ modes}$$

So, total no. of guided modes will be integer closest to and greater than $N = \frac{2V}{\pi}$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri
Physics

Now, thus this condition gives you twice m plus 2 modes and if this V lies between twice m pi by 2 and twice m plus 1 pi by 2 between them, then the total number of modes in the same way will be twice m plus. That means whether you are at the symmetric mode or you are at the anti symmetric mode as the last point of intersection. So, in these way you can generalize the condition that the total number of modes supported, in the in the waveguide will be a integer which is closest to or greater than this twice V by pi. So, this is a very beautiful finding and it is used for determining the properties of the waveguide when we know the V number.

(Refer Slide Time: 23:44)

Many modes

When the waveguide supports many modes, (i.e., $V \gg 1$)

then the point of intersection for solutions are very close to $x = \frac{\pi}{2}, \pi, \frac{3\pi}{2}, \dots \text{etc.}$

The propagation constant of first few modes will be approximately given by

$$\frac{\kappa d}{2} = x = x_m = \sqrt{k_0^2 n_1^2 - \beta^2} \cdot \frac{d}{2} \approx (m + 1) \frac{\pi}{2}$$

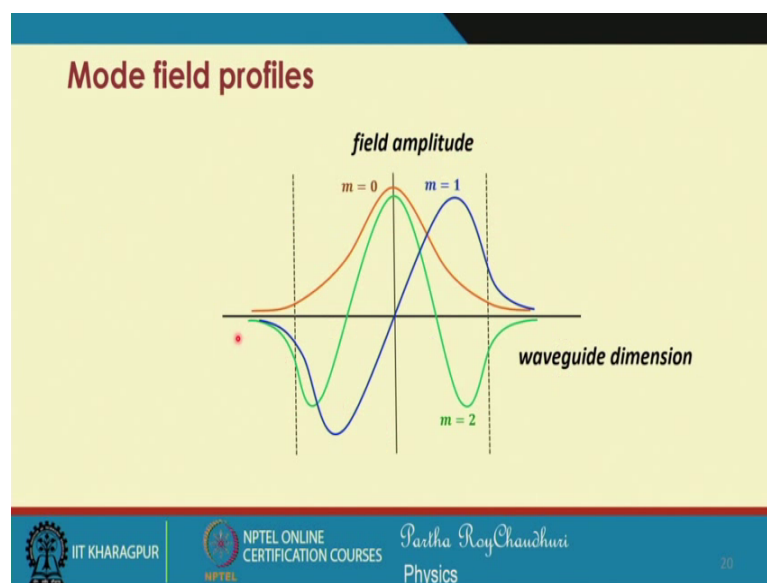

where, $m = 0, 2, 4 \dots \dots \text{sym}$
 $m = 1, 3, 5 \dots \dots \text{antisym}$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, it tells you that this V number gives you many modes that is $k d$ by 2 equal to x this approximately equals to this quantity. So, the point of intersections are the solution so this is a rough way of estimating the propagation constants for the various modes because, this at the cutoff at this point x equal to π by 2 these are very close points you can just have a look at it this is very close to π this is also very close to π by 2. But this will be even more closer when you approach for large number of modes, so therefore, an empirical way of finding the mode parameters the mode the mode propagation constants by using this relation ok.

(Refer Slide Time: 24:34)

So, these are the mode field distribution you can see for m equal to 0 you have this symmetric mode which is called the fundamental mode m equal to 0, for m equal to 1 you have the anti symmetric mode and for m equal to 2 you have again the symmetric mode. So, these are the modes which will be supported in the structure.

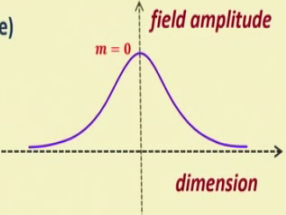

(Refer Slide Time: 24:57)

Single-mode operation

When $0 < V < \frac{\pi}{2}$ → one sym.

The waveguide supports **JUST one mode** (TE-mode)
This mode is symmetric about x

We call this waveguide a **single-moded one**

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri
Physics

When V is less than 0 V is greater than 0, but less than 2 you have one symmetric mode. So, for this regime of operation when I choose the waveguide parameters in such a way including the wavelength, such that the V number falls between 0 and π by 2 then the structure we support only one mode and that is the fundamental mode such a waveguide is called a single mode waveguide at that operating wavelength and you see that this mode will be symmetric about x . All the even modes that is n m equal to 0 2 4 etcetera will be all symmetric modes, so we have a and we call this wave waveguide as a single mode waveguide which is very relevant and very important in the study of in the in the in the signs of optical waveguide.

(Refer Slide Time: 25:53)

Single-mode condition

For single-mode operation: $V = k_0 \frac{d}{2} \sqrt{n_1^2 - n_2^2} = \frac{2\pi d}{\lambda_0} \frac{d}{2} \sqrt{n_1^2 - n_2^2} \leq \frac{\pi}{2}$

Therefore, the condition is: $d \leq \frac{1}{2} \frac{\lambda_0}{\sqrt{n_1^2 - n_2^2}}$

So, if the waveguide dimension, d , core and cladding RI's n_1, n_2 and the wavelength of operation, λ_0 are such that above relation holds-
the waveguide supports **one mode, fundamental TE mode**
and is referred to as operating in the **single-mode regime**

Physics

For single mode operation V equal to V equal to this quantity because we have defined this, so therefore the condition d is equal to half of $\lambda_0 \sqrt{n_1^2 - n_2^2}$. So, if the waveguide dimension that is core refractive index and λ_0 are such that they satisfy this condition, then you automatically take care of the single mode nature of the waveguide the waveguide supports one fundamental TE modes and it is referred to as the single mode regime of operation.

(Refer Slide Time: 26:28)

Example: Single-mode waveguide

Consider a situation:

The core and cladding RI's are $n_1 = 1.50, n_2 = 1.48$
the wavelength of operation $\lambda_0 = 1.5 \mu\text{m}$

$$d \leq \frac{1}{2} \frac{1.5}{\sqrt{1.50^2 - 1.48^2}} \leq 3.07 \mu\text{m}$$

required waveguide dimension $d = 3.07 \mu\text{m}$
waveguide operates as **single-moded one** for all wavelengths below $\lambda_0 = 1.5 \mu\text{m}$

IIT KHARAGPUR

NPTEL ONLINE
CERTIFICATION COURSES

Let us take an example the core and cladding refractive indices are n_1 equal to this, which are the typical values for glass and planar optical waveguides and the wavelength of operation is it is equal to 1.5 micrometer. If you plug in this values in the in the relation here then you get the value of d which is very close to 3.07 micrometer. If the waveguide dimension is less than this wavelength of operation is this or below this and the refractive indices of the core and cladding are these, then this waveguide will be a single mode one for all wavelengths which are below λ_0 equal to 1.5.

Cut-off: TE- mode

- ✓ For guided modes, $n_2^2 < \frac{\beta^2}{k_0^2} < n_1^2$.
- ✓ That means for a guided mode β can not be less than $k_0 n_2$.
- ✓ At this value of β , the mode ceases to propagate
- ✓ i.e., what is called the **cut-off** of the mode.

✓ Hence, $\beta = k_0 n_2; \gamma = 0 \Rightarrow V^2 = \left(\frac{\kappa d}{2}\right)^2 + \left(\frac{\gamma d}{2}\right)^2 \Rightarrow V = \frac{\kappa d}{2} = x$

Then, $x \tan x = 0$ i.e., $V \tan V = 0$ **for sym**

Also, $x \cot x = 0$ i.e., $V \cot V = 0$ **for antisym**

Physics

Then the cutoff property for guided modes you have this property because, anyway the propagation constant has to lie between these for every mode. Now if they are critically equal that is $k_0 n_2$ is equal to $B^2 \beta^2$ then that is what we call the cutoff so that gives you the condition. So, if γ that is $k_0 n_2$ minus β^2 square will become equal to 0 that is equal to γ equal to 0, because of this condition so that tells you V equal to κd by 2 which is equal to x . So, $x \tan x$ equal to 0 from the eigenvalue equation and $x \cot x$ will be equal to 0 these are the conditions for symmetric and anti symmetric modes and V end up with this condition that tells you for $V \cot V$ will be equal to 0, $V \cot$ will be equal to $m \pi$ to get this condition equal to 0.

(Refer Slide Time: 28:11)

Cut-off: TE- mode

$V \tan V = 0$ for sym

$V \cot V = 0$ for antisym

The cut-off V values for various modes are $V_c = m\pi$ $\begin{cases} m = 0, 2, 4, \dots \dots \text{sym} \\ m = 1, 3, 5, \dots \dots \text{antisym} \end{cases}$

- ✓ Even and odd m values correspond to cut-off of symmetric and antisymmetric modes
- ✓ And fundamental mode has no cut-off, i.e, fundamental mode will be always present

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri Physics

So, so that is so I just roughly take the value of m equal to 1 2 3 that gives me the value of V_c , the cutoff V value at which and below which those modes will be supported. Fundamental mode has no cutoff because, you whenever there is some excitation it is always the fundamental mode and you can see from this equation also that there is no cutoff for the fundamental mode it is always present in the waveguide.

(Refer Slide Time: 28:47)

Symmetric RI profiles

Now consider a symmetric waveguide

Then the RI profile can be written as: $n^2(-x) = n^2(x)$

For TE modes the wave equation is

$$\frac{d^2 E_y(x)}{dx^2} + k_0^2 n^2(x) E_y = \beta^2 E_y(x);$$

Transforming $x \rightarrow -x$ wave equation becomes

$$\frac{d^2 E_y(-x)}{dx^2} + k_0^2 n^2(-x) E_y = \beta^2 E_y(-x);$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri Physics

Now, there is one issue one important point that if you consider a symmetric refractive index profile of the waveguide you can write this mathematically like this and for TE

modes you can write down this equation which is an eigenvalue equation. If you transform x to $-x$ I can write this equation like this, you can see that both the equations I mean both the both the $E_y(x)$ and $E_y(-x)$ they satisfy the same equation.

(Refer Slide Time: 29:18)

Symmetric RI profiles

So we see that
both $E_y(x)$ and $E_y(-x)$ satisfy the same equation
Hence, $E_y(x)$ and $E_y(-x)$ are eigenfunctions with same eigenvalue β
So these are either degenerate states
OR $E_y(-x)$ must be a multiple of $E_y(x)$

$$E_y(-x) = \lambda E_y(x)$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri
Physics

So, both E_y and E_y of $-x$ satisfy the same equation hence these 2 are the Eigen functions with the Eigen value. So, this means that these 2 are the degenerate steps or it could be that this must be a multiple of E_y . So, this possibility of degenerate sets can also be shown to be the identically the same consequence. But if we consider E_y of $-x$ equal to λ times this, this will then again you transform this x to $-x$ that is E_y of x will become λ into E_y .

(Refer Slide Time: 29:54)

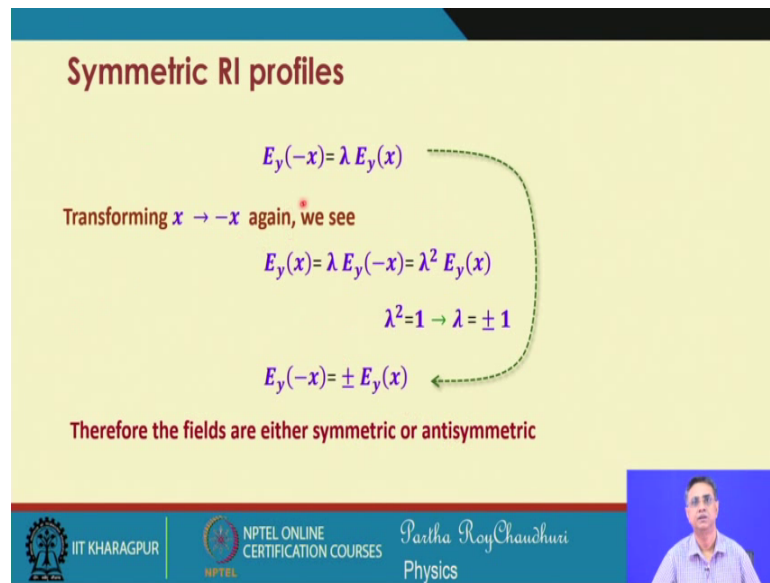

Symmetric RI profiles

$$E_y(-x) = \lambda E_y(x)$$

Transforming $x \rightarrow -x$ again, we see

$$E_y(x) = \lambda E_y(-x) = \lambda^2 E_y(x)$$
$$\lambda^2 = 1 \rightarrow \lambda = \pm 1$$
$$E_y(-x) = \pm E_y(x)$$

Therefore the fields are either symmetric or antisymmetric

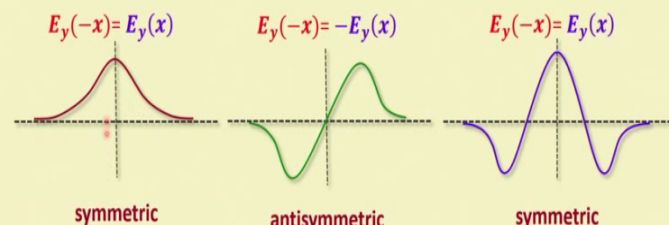

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri
Physics

So, I put minus x again put back x equal to minus x which gives you that lambda square equal to 1, so that is lambda equal to plus minus 1. That means, E_y of minus x is equal to plus minus this is this is very clearly the condition of the symmetric nature of the symmetric and anti symmetric nature of the mode profile. So, therefore if the fields are either symmetric or anti symmetric provided that the refractive index profile is of symmetric nature.

(Refer Slide Time: 30:29)

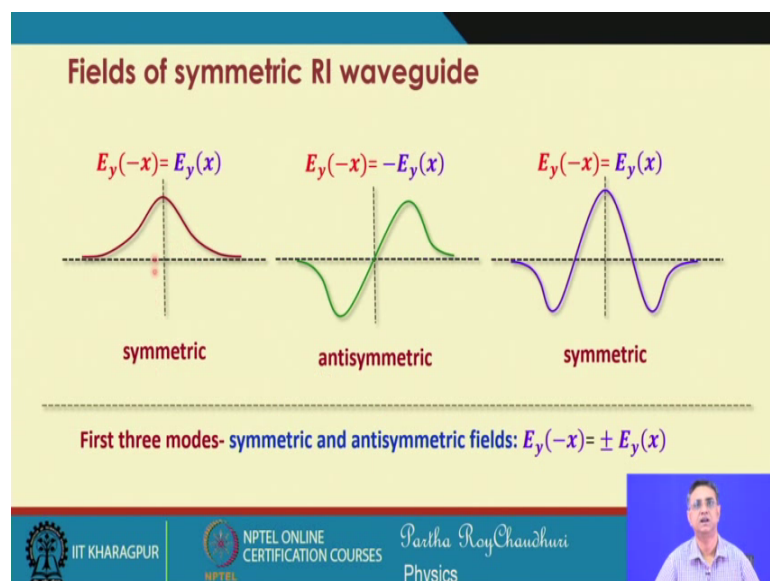

Fields of symmetric RI waveguide

$E_y(-x) = E_y(x)$ $E_y(-x) = -E_y(x)$ $E_y(-x) = E_y(x)$

symmetric antisymmetric symmetric

First three modes - symmetric and antisymmetric fields: $E_y(-x) = \pm E_y(x)$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri
Physics

So, you can see that E_y of minus x equal to E_y of x is a symmetric field, but E_y of minus x equal to minus E_y of x then it is anti symmetric and so on. So, these are the these are the consequence of a symmetric refractive index profile.

(Refer Slide Time: 30:47)

-----Summary of discussions-----

- ✓ Symmetric Slab waveguides, TE –modes , eigenvalue equations, symmetric and antisymmetric modes
- ✓ V number, number of modes , field distributions, single-mode operation, cut-off properties, symmetric RI profiles

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri
Physics

Now, I conclude here by saying that the we discussed this symmetric slab waveguides for the TE modes we will take up the TM modes next. We discussed the eigenvalue equations and then symmetric and anti symmetric modes even and odd modes which are supported by this waveguide, we have try to depict the mode pictures also mode profiles. Discussed the V number then from the V number how we can evaluate you can estimate the number of modes that will be supported, field distribution of the modes then very very particular thing about the optical waveguides is the single mode operation for this slab waveguide that also we have discussed.

Then we discussed the cutoff properties symmetric refractive index profile and the consequence of that in terms of symmetric and anti symmetric field profiles.

Thank you.
