Lecture - 35
Electro-optic Modulators and Devices (Contd.)

So, we are discussing the Electro-optics of Anisotropic Medium and we considered this very important crystal KDP and we were looking at the birefringence retardation.

(Refer Slide Time: 00:32)

Contents

- ✓ Longitudinal configuration of **KDP**, **phase modulation**, Induced birefringence, induced phase change, half-voltage
- ✓ Phase **modulation index**, **side bands**, power transfer
- ✓ Phase retardation, basic setup of **amplitude modulation**

 IIT KHARAGPUR |  NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri
Physics

Now, in this longitudinal configuration of KDP, we will be discussing this phase modulation and in phase modulation we will look at the induced birefringence, induced phase change and half voltage once again. Then we will look at the theoretical consideration of the phase modulation, then how it generates the sidebands, and how power is transferred to the sidebands depending on the applied voltage. Then we will look at the phase retardation and the basic setup corresponding to the amplitude modulation because the same configuration, but with polarizer and analyzer one can make use of this setup as a amplitude modulation device.

(Refer Slide Time: 01:25)

Longitudinal configuration of KDP

Phase Modulation

The slide features a yellow background with a blue header and footer. The title 'Longitudinal configuration of KDP' is in red, and 'Phase Modulation' is in green and underlined. The footer contains the IIT Kharagpur logo, NPTEL logo, and the text 'Partha RoyChaudhuri Physics'. A small video feed of the lecturer is in the bottom right corner.

(Refer Slide Time: 01:30)

Longitudinal configuration

The diagram shows a 3D rectangular crystal with a coordinate system (x, y, z) inside. A light beam, represented by three parallel purple arrows, enters from the left and exits to the right, traveling along the z-axis. A voltage V is applied across the crystal along the x-axis, with a double-headed arrow labeled l indicating the length of the crystal in the x-direction. The thickness of the crystal in the y-direction is labeled d . The text 'Longitudinal configuration' is centered below the diagram.

The slide features a yellow background with a blue header and footer. The diagram is centered on the slide. The footer contains the IIT Kharagpur logo, NPTEL logo, and the text 'Partha RoyChaudhuri Physics'. A small video feed of the lecturer is in the bottom right corner.

So, for longitudinal configuration phase modulation, once again this is the setup you have a light beam which is traveling through the crystal of length l and have applied a voltage V variable voltage. So, the electric field is V upon l ; and this is the schematic of this you have an applied beam.

(Refer Slide Time: 01:48)

You can see that because the direction of the applied the field voltage application and the beam propagation they are same, so you have to use a transparent electrode. There are electrodes with a narrow hole that is also used and commercially available.

(Refer Slide Time: 02:12)

Induced birefringence

Longitudinal configuration of KDP

$$n_{x'} = n_0 - \frac{n_0^3}{2} r_{63} E_z \quad n_{y'} = n_0 + \frac{n_0^3}{2} r_{63} E_z \quad n_{z'} = n_e$$

Induced birefringence: $\Delta n_{x'y'} = n_0^3 r_{63} E_z = n_0^3 r_{63} V/l$

Induced phase change: $\Delta\phi = k_0 l \Delta n_{x'y'} = k_0 l n_0^3 r_{63} V/l$

So, induced birefringence in this case we have seen that this new principal refractive index for x that is $n_{x'}$ is equal to this and the same for $n_{y'}$ is equal to this, $n_{z'}$ remains the same that is extraordinary refractive index value of the crystal. Therefore, the birefringence between this x' and y' in presence of the external

electric field which is applied along the longitudinal direction that is E_z . So, that is equal to $\Delta n \times \text{prime } y \text{ prime}$ is equal to this sum of this quantity and this quantity.

So, this is your induced birefringence and induced phase change will be this multiplied by your k_0 that is twice π by λ which will be effectively 1 cancels, so k_0, n_0^3 into V . So, we can see that induced phase change is proportional to the applied voltage. We will recall that. If we restrict our polarization to one of these $x \text{ prime}$ or $y \text{ prime}$ direction by placing the polarizer making an angle of 45 degree with the old coordinate axis that is normal natural coordinate axis of the crystal then it will excite either x axis, $x \text{ prime}$ axis or we can orient along $y \text{ prime}$ axis.

Let us suppose if we excite only $x \text{ prime}$ axis then with voltage only this much of the change in the refractive index in addition to n_0 will be modulated by this external voltage and the light that will be emerging out of the crystal will be phase modulated by this quantity. Whereas for y polarized $y \text{ prime}$ polarized light this quantity will be the modulation in the phase this will correspond to this will give rise to the modulation in the phase. And we will see this here we have calculated the birefringence between this $x \text{ prime}$ and $y \text{ prime}$ as if the polarization is along 45 degree with $x \text{ prime}$ and $y \text{ prime}$.

(Refer Slide Time: 04:57)

Half-voltage

The induced phase shift:

$$\Delta\phi = k_0 l n_0^3 r_{63} \left(\frac{V}{l}\right)$$

Therefore, $\Delta\phi \propto V$: variable retardation

Modulator half-voltage :

$$\pi = \frac{2\pi}{\lambda} l n_0^3 r_{63} \left(\frac{V}{l}\right)$$

$$V_\pi = \frac{\lambda}{2n_0^3 r_{63}}$$

IIT KHARAGPUR

NPTEL ONLINE
CERTIFICATION COURSES

Partha RoyChaudhuri

Physics

So, in that case this with this induced birefringence $\Delta\phi$ again we find that $\Delta\phi$ the change in the phase is proportional to V . Again this gives you a variable retardation and modulator half voltage is this we just have to which is the same we just have to use

the value of the r_{63} coefficient to get the half voltage of the crystal. It does not involve any length or any width of the crystal, it is simply proportional to the wavelength and inversely proportional to the electro-optic coefficient.

(Refer Slide Time: 05:42)

Longitudinal EO modulator

- ✓ with applied electrical field $E = V/l$
- ✓ the induced phase shift is $\Delta\Phi = \pi$
- ✓ which is independent of the length l
- ✓ linearly proportional to the voltage V

IIT KHARAGPUR

NPTEL ONLINE
CERTIFICATION COURSES

Partha RoyChaudhuri

Physics

So, with applied voltage V upon l the induced phase shift for this half voltage is equal to π which is independent of length l and is linearly proportional to the applied externally applied voltage.

(Refer Slide Time: 06:01)

Phase modulation

The induced phase shift:

$$\Delta\phi = k_0 L n_0^3 r_{63} \left(\frac{V}{L}\right)$$

Modulator half-voltage :

$$V_\pi = \frac{\lambda}{2n_0^3 r_{63}}$$

IIT KHARAGPUR

NPTEL ONLINE
CERTIFICATION COURSES

Partha RoyChaudhuri

Physics

Now, for phase modulation we have seen that this $\Delta\phi$ will be equal to this and V_{π} modulator half voltage will be this, and this is the configuration that you have to excite the polarization input polarization which will be coinciding with either x axis or y axis and light will be travelling along z axis. Then the light which is coming out of the crystal will be a only x prime polarized, but the phase will be modulated because the phase the refractive index is being modulated by the external applied voltage and we will see this.

(Refer Slide Time: 06:45)

The slide has a yellow background with a blue header and footer. The title 'Phase modulation: Longitudinal' is in purple, and the subtitle 'Input light polarised along x' or y' axis' is in green. The footer contains the IIT Kharagpur logo, NPTEL logo, and the text 'Partha Roy Chaudhuri Physics'. A small video inset of the speaker is in the bottom right corner.

So, in the case of phase modulation for the longitudinal case input polarized light is either x prime or y prime axis. So, this is the thing that we will always have to remember that if you are looking for if you want to configure the device for phase modulation then the input polarization will be either x prime or y prime, not with 45 degree with x and y.

(Refer Slide Time: 07:16)

So, let us first consider and in the case of phase polarized phase modulation the light which will be available emerging out of the crystal, when there is no modulation. So, this will be the phase you can see that there is an uniform phase propagation, but if you have a modulating voltage which is sinusoidal then you can see that at the periods of the modulating voltage the waveform is compressed and verified.

So, this modulation information is impressed on the on the optical wave which is coming out of the crystal, ok.

(Refer Slide Time: 07:59)

So, for phase modulation as I have mentioned that this light has to be launched with polarization with x prime or y prime. Let us suppose we consider that light is polarized along x prime axis and that is easy for this crystal because we know that it makes an angle of 45 degree with the old x or y axis. So, it is a very easy to locate that this the x prime axis which will be half way between the x and y axis of the crystal and z axis is the propagation direction voltage is applied in the longitudinal direction of the crystal of length l.

(Refer Slide Time: 08:47)

Consider a KDP crystal

- ✓ a linearly polarised light propagates in it along z-direction
- ✓ the input polarisation makes an angle of 45° with x-axis
- ✓ polarised along x' , the principal axis in presence of E-field

Now for a KDP crystal

- ✓ index ellipsoid in absence of field

$$\frac{x^2}{n_o^2} + \frac{y^2}{n_o^2} + \frac{z^2}{n_e^2} = 1$$

The slide features a yellow background with blue and orange text. At the bottom, there is a blue banner with the IIT Kharagpur logo and NPTEL Online Certification Courses text. A small video inset of a speaker is visible in the bottom right corner.

So, first case we considered that the input light is x polarized, then 45 degree with the x that is x polarized and then for this setup index ellipsoid without the electric field is already known. Now, we will we will consider the electric field which is longitudinal, but now how it affects the x prime direction refractive index.

(Refer Slide Time: 09:11)

In absence of E -field

- ✓ light launched with polarisation at 45° to x or y does not see any birefringence since both RI's $n_x = n_0$ and $n_y = n_0$

In presence of E -field

- ✓ input light polarised at 45° to x axis sees RI of the medium

$$n_{x'} = n_0 - \frac{n_0^3}{2} r_{63} E_z$$

The slide features a yellow background with blue and red text. At the bottom, there is a blue banner with the IIT Kharagpur logo, the text 'IIT KHARAGPUR', and the NPTEL logo with the text 'NPTEL ONLINE CERTIFICATION COURSES'. A small video inset of a presenter is located in the bottom right corner of the slide area.

So, in absence of the field n_x equal to n_0 , n_y equal to n_0 , n_z is anyway equal to n_e and that is not useful here. In presence of the electric field input light is polarized at 45 degree with x that is along x' prime direction that is the new principal refractive index direction. So, it is the crystal we will see only a light which is polarized along x' prime and there is no other component.

So, as a result this refractive index that is experienced by the light of x' prime polarization we see this quantity as because of the presence of the electric field. So, this is the quantity which will be in excess of the n_0 that is the natural refractive index and as E_z changes this quantity will be modulated.

(Refer Slide Time: 10:17)

So, for this configuration phase of the light can be altered by an electric field across the crystal if I apply a modulating voltage which is $V = V_0 \sin \omega_m t$, ω_m stands for modulating frequency. So, with this frequency if I modulate the external voltage which is applied along the length of the crystal then the phase of the light which is traveling through the crystal will be modulated.

(Refer Slide Time: 10:59)

The wave emerging from the crystal

$$E_{x'}(z=l) = E_{x'}(0) \cos(\omega t - k_0 n_x l)$$

$$E_{x'}(z=l) = E_{x'}(0) \cos\left(\omega t - k_0 \left(n_0 - \frac{n_0^3}{2} r_{63} E_z\right) l\right)$$

$$E_{x'}(z=l) = E_{x'}(0) \cos\left(\omega t - k_0 n_0 l + k_0 \frac{n_0^3}{2} r_{63} E_z l\right)$$

$\downarrow$ $\downarrow$
fixed δ $V = V_0 \sin \omega_m t$

$$E_{x'}(z=l) = E_{x'}(0) \cos\left(\omega t - \delta + k_0 \frac{n_0^3}{2} r_{63} V_0 \sin \omega_m t\right)$$

The slide includes IIT Kharagpur and NPTEL logos.

So, in that case $E_{x'}$ at z equal to l that is at this point will be modified at z equal to 0, at z equal to 0 $E_{x'}$ and then cosine ωt . So, this is the this is the new

refractive index multiplied by k_0 , will be the additional phase because of the presence of the voltage otherwise it would have been k_0 and n_0 only into l of course, and so this one can write in this form that $k_0 n_0 l$ because n_0 is anyway known to us. So, we can write in this form. Then from here if you open the bracket $k_0 n_0 l$ this quantity is fixed and this is the natural phase because of the propagation of the light through a length l , but this one is the phase which is because of the electric field E_z for over and for propagation of length l .

So, here this E_z into l is nothing but $E_0 \sin \omega_m t$ as per our assumption. So, this from this we can write this equation as $E_0 \cos(\omega t - \delta + \text{fixed phase})$ and this is the phase which is undergoing the modulation because of this voltage. So, we can write this equation in this form.

(Refer Slide Time: 12:41)

$$E_{x'}(z=l) = E_{x'}(0) \cos\left(\omega t - \delta + k_0 \frac{n_0^3}{2} r_{63} V_0 \sin \omega_m t\right)$$

$$E_{x'}(z=l) = E_{x'}(0) \cos(\omega t - \delta + p \sin \omega_m t)$$

Here $p = \frac{k_0 n_0^3}{2} r_{63} V_0$ is the phase modulation index

the sinusoidal variation of output light with peak value p

And therefore, because this quantity is anyway constant V_0 is the peak voltage this is constant this is constant wavelength of operation is constant. So, in place of this we can write a new constant p , then this equation becomes $\omega t - \delta + p \sin \omega_m t$. This p is the phase modulation index which is again well known, this is the quantity the peak value of the modulation, the sinusoidal variation of the output light with the peak value of p , so that will be the modulation index, right.

(Refer Slide Time: 13:21)

Now use the following identities:

$$\cos(p \sin \omega_m t) = J_0(p) + 2J_2(p) \cos 2\omega_m t + 2J_4(p) \cos 4\omega_m t + \dots$$
$$\sin(p \sin \omega_m t) = 2J_1(p) + 2J_3(p) \sin 3\omega_m t + \dots$$

And the trigonometric identities:

$$2\cos A \cos \theta = \cos(A - \theta) + \cos(A + \theta)$$
$$2\sin B \sin \theta = \cos(B - \theta) - \cos(B + \theta)$$

Now, use the following identities that is for because you have $p \sin \omega_m t$ we can write this cosine of $p \sin \omega_m t$. This is again a very well known identity and for p repair of identities $p \sin$ of $p \sin \omega_m t$ which is equal to this. Then we will also use this trigonometric identities that is twice cosine $A \cos \theta$ can be written as the sum and difference of A and θ , similarly B and θ can be expressed as a sum and difference of B and θ .

(Refer Slide Time: 14:12)

So rewrite the output field as:

$$E_x(z=l) = E_x(0) \{$$
$$J_0(p) \cos(\omega t - \delta)$$
$$+ J_1(p) \cos[(\omega + \omega_m)t - \delta]$$
$$- J_1(p) \cos[(\omega - \omega_m)t - \delta]$$
$$+ J_2(p) \cos[(\omega + 2\omega_m)t - \delta]$$
$$+ J_2(p) \cos[(\omega - 2\omega_m)t - \delta]$$
$$+ \dots$$
$$\}$$

Therefore, this equation this equation can now be written in this form that E_x at z equal to 1 will be $E_0 x$ and then $p \cos \omega_m t$ can be expressed as the superposition of these various order Bessel functions. If we collect the collect the Bessel functions J_0, J_1, J_2, J_3 together J_1, J_2 together and so on we can write this in this form.

(Refer Slide Time: 14:37)

The phase modulated wave contains

- ✓ wave at fundamental frequency ω with amplitude $J_0(p)$
- ✓ in addition, the output light contains various side-bands
- ✓ at frequencies $\omega \pm \omega_m, \omega \pm 2\omega_m$ etc.
- ✓ with amplitude $J_1(p), J_2(p), J_3(p)$ etc.

also, when $p = \frac{k_0 n_0^3}{2} r_{63} V_0 = 2.4048, J_0(p) = 0$
 power is completely transferred to the side-bands

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

The phase modulated wave then contains wave at frequency ω with amplitude $J_0(p)$. Look at this after doing this algebra we can see that it contains the modulated output wave at z equal to 0, it contain a wave whose amplitude is Bessel J_0 of p with fundamental frequency ω . But it also contains $J_1 \omega$ plus ω the modulated frequency modulating frequency has got into this fundamental frequency the original frequency and here so this is the sum of the of the frequency of the light plus the modulating frequency this is the difference they are associated with J_1 . For J_2 this the amplitude of the light with J_2 will have frequency ω plus twice ω_m and ω minus twice ω_m .

So, we get we can find that in addition to this original frequency there are sidebands at equal intervals ω plus ω_m , ω minus ω_m ω plus twice ω_m ω minus twice ω_m and so on. So, it also excites the sidebands as well in addition to the original frequency. So, that is what is there that the output light contains various sidebands at frequencies ω plus minus ω_m and so on and so forth with amplitude $J_1(p), J_2(p), J_3(p)$ etcetera.

And also that p because the value of p is known by knowing this k_0 twice π by λ for a given wavelength n_0 the ordinary refractive index that is also known, then this coefficient electro-optic coefficient is also known and assuming a certain value of the peak voltage that is applied across the crystal. This p if it coincides with these value 2.4048, this number is very important and very useful particularly in fiber optics where Bessel functions are there.

So, this is this will give you the 0 of the Bessel function of the Bessel function J_0 . So, at this value p equal to 2.4048 J_0 will become equal to 0 and in that case there is no power in the J_0 , but the complete power transfer will take place from this J_0 to the sideband that is J_1, J_2, J_3 etcetera. So, all the power will be transferred to the sidebands, but there is no power in the in the J_0 that is original frequency, ok.

(Refer Slide Time: 17:35)

Now, let us suppose that if we assume the polarization of the input light is now along new y' axis that is it is again 45 degree with the old that is the natural a principal axes x and y , but with a 45 degree, 90 degree, at 90 degree with the x axis.

So, this $x y'$ polarization if we launch light then the output light is again phase modulated, it will happen the same way as it had happened in the case of $x y'$ polarization light.

(Refer Slide Time: 18:18)

The wave emerging from the crystal

$$E_{y'}(z=l) = E_{y'}(0) \cos(\omega t - k_0 n_y l)$$

$$E_{y'}(z=l) = E_{y'}(0) \cos\left(\omega t - k_0 \left(n_0 + \frac{n_0^3}{2} r_{63} E_z\right) l\right)$$

$$E_{y'}(z=l) = E_{y'}(0) \cos\left(\omega t - k_0 n_0 l - k_0 \frac{n_0^3}{2} r_{63} E_z l\right)$$

fixed δ $V = V_0 \sin \omega_m t$

$$E_{y'}(z=l) = E_{y'}(0) \cos\left(\omega t - \delta - k_0 \frac{n_0^3}{2} r_{63} V_0 \sin \omega_m t\right)$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

And then we can write this equation once again we can just repeat for y prime and that will lead to this fixed value of fixed value of the phase which is due to the natural due to the original the refractive index ordinary refractive index length and in the same way we can expect this.

(Refer Slide Time: 18:42)

Polarisation dependent output

Input light x' polarized

$$E_{x'}(z=l) = E_{x'}(0) \cos\left(\omega t - \delta + k_0 \frac{n_0^3}{2} r_{63} V_0 \sin \omega_m t\right)$$

Input light y' polarized

$$E_{y'}(z=l) = E_{y'}(0) \cos\left(\omega t - \delta - k_0 \frac{n_0^3}{2} r_{63} V_0 \sin \omega_m t\right)$$

Input light is x or y polarized, i.e., 45° with x' or y'

Birefringence between the x' and y' components

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Therefore for input polarized for input light with polarization x prime we have this output E_{x0} at the input and then cosine of this quantity, but if the input polarization is y

polarized y dash polarized then the output polarization output waveform will have this expression this form.

Now, we have separately calculated the input polarization for x prime and also for y prime. Now, we will consider that if it is half wave through that if the input polarization is along x or y that is the old principal axes that is 45 degree with x prime or y prime axis in that case the birefringence between this x prime and y prime will now be calculated.

(Refer Slide Time: 19:43)

Phase retardation

Now assume that

- ✓ input light is x or y polarized, i.e., 45° with x' or y'
- ✓ Input light decomposed into x' and y' polarisations of equal amplitude
- ✓ At $z = 0$ x' and y' polarisations have same phase
- ✓ At $z = l$ retardation between the two components

$$\Delta\phi = k_0 n_0^3 r_{63} E_z l = k_0 n_0^3 r_{63} V$$

The slide is a presentation slide with a yellow background and a blue header. It contains a title 'Phase retardation', a sub-header 'Now assume that', and four bullet points. The last bullet point is followed by a boxed formula. The slide is part of an NPTEL online certification course from IIT Kharagpur, as indicated by the logos at the bottom.

So, in that case you will have this birefringence $\Delta\phi$ which will be just the sum of these two quantities, the sum of these two quantities. This one is due to the y polarized y prime polarized light and this is for the x prime polarized light, right. So, we calculate the birefringence in this case.

(Refer Slide Time: 20:06)

Phase retardation

- ✓ Between x' and y' the retardation

$$\Delta\phi = k_0 n_0^3 r_{63} E_z l = k_0 n_0^3 r_{63} V$$

- ✓ proportional to the applied voltage
- ✓ no applied voltage no retardation
- ✓ this configuration forms the basis of amplitude modulation

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

And between x dash and y dash the retardation will be equal to this which is again the proportional to the external the applied voltage V , and if there is no applied voltage there is no retardation. So, V equal to 0; that means $\Delta\phi$ equal to 0 which is very obvious and this configuration that is the basis of the amplitude modulation.

As I have mentioned that if you launch light only with x prime or y prime then the output light will be phase modulated. But if you launch light with input polarization which is 45 degree with x prime and y prime that is if the input polarization is with any of the old x or y axis along x or y axis in that case and if you place an analyzer at the output which is cross with the input then the system will give you amplitude modulation.

(Refer Slide Time: 21:16)

Longitudinal configuration of KDP

Amplitude Modulation

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri
Physics

The slide features a yellow background with a blue header and footer. The title 'Longitudinal configuration of KDP' is in red and blue, and the subtitle 'Amplitude Modulation' is in black and underlined. The footer contains logos for IIT Khargapur and NPTEL, along with the speaker's name and subject.

(Refer Slide Time: 21:19)

Amplitude modulation: Longitudinal

Input light polarised along x or y axis

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri
Physics

This slide has a yellow background with a blue header and footer. The title 'Amplitude modulation: Longitudinal' is in blue, followed by a horizontal line and the subtitle 'Input light polarised along x or y axis' in purple. The footer includes the same logos and speaker information as the previous slide.

So, in the longitudinal configuration case the amplitude modulation requires that light will now be polarized along x or y which are the old coordinate systems that is the old the principal axes system of the crystal without any external field.

(Refer Slide Time: 21:33)

Amplitude modulation: Longitudinal setup

A half-wave plate requires a voltage $V_{\pi} = \frac{\lambda}{2n_0^3 r_{41}}$

NPTEL ONLINE
CERTIFICATION COURSES

Partha RoyChaudhuri

Physics

So, in that case we have light which is polarized with this thick blue dash line and you have an analyzer a polarizer which is along this direction and the light travels through this and you have a crossed analyzer a polarizer which is which is which is working as an analyzer in that case the output light will be amplitude modulated. And we will have a half wave plate voltage that is required for this is equal to V_{π} which is λ by twice $n_0^3 r_{41}$. So, this would be r_{41} , this would be r_{63} .

(Refer Slide Time: 22:27)

Phase retardation: longitudinal KDP

phase retardation between x' and y'

$$\Delta\phi = k_0 n_0^3 r_{63} E_z l = k_0 n_0^3 r_{63} V$$

assume typical values for KDP crystal

$r_{63} = 10.5 \times 10^{-12} \text{ m/V};$	$\lambda = 0.5 \mu\text{m};$
$n_0 = 1.512;$	$V = 10 \text{ kV}$
$l = 1 \text{ cm};$	

NPTEL ONLINE
CERTIFICATION COURSES

Partha RoyChaudhuri

Physics

So, this phase retardation between x and y prime will be equal to this. Assume this typical values of this KDP crystal which we have used earlier also that is r_{63} equal to this, n_0 equal to this, and length of the crystal which anyway does not come as per as the voltage is concerned, so, and V equal to this 10 kilo volt lambda 500 nanometer.

(Refer Slide Time: 22:57)

longitudinal KDP: half voltage

Half Voltage at $\lambda = 0.6 \mu m$

$$V_{\pi} = \frac{\lambda}{2 n_0^3 r_{63}}$$

$$= \frac{0.6 \times 10^{-6}}{2(1.512)^3 \times 10.5 \times 10^{-12}}$$

$$= 8.3 \text{ KV}$$

NPTEL ONLINE
CERTIFICATION COURSES

Then the half voltage for lambda equal to 5 but here we have used lambda equal to 6.

(Refer Slide Time: 23:00)

Phase retardation: longitudinal KDP

phase retardation between x' and y'

$$\Delta\phi = k_0 n_0^3 r_{63} E_z l = k_0 n_0^3 r_{63} V$$

assume typical values for KDP crystal

$r_{63} = 10.5 \times 10^{-12} \text{ m/V};$	$\lambda = 0.5 \mu m;$
$n_0 = 1.512;$	$V = 10 \text{ kV}$
$l = 1 \text{ cm};$	

NPTEL ONLINE
CERTIFICATION COURSES

So, for 0.6 micrometer lambda this V_{π} will be equal to 6.3 kilo volt and that we have seen also earlier.

(Refer Slide Time: 23:19)

----- Summary of discussion -----

- ✓ Longitudinal configuration of KDP, phase modulation, Induced birefringence, induced phase change, half-voltage
- ✓ Phase modulation index, side bands, power transfer
- ✓ Phase retardation, basic setup of amplitude modulation

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri
Physics

So, we discussed the longitudinal configuration of KDP in terms of its phase modulation, and we have seen that for phase modulation it requires the input polarization to be along the new principal refractive indices one of the new principal refractive indices direction.

Then, will calculated the induced birefringence, induced phase change and half voltage. Then in this configuration we also evaluated theoretically the phase modulation index sidebands and how the power is transferred to the sidebands for a given value of the modulation index p which is equal to 2.4048 that is the Bessel J_0 is 0. Then for amplitude modulation we will looked at the phase retardation and the basic setup, and how it can be used as an amplitude modulation which across polarizer at the input and output that also we have discussed.

Thank you.
