Lecture – 41
Acousto-optic Effect

In the previous sections, we have discussed Electro optic Effect and we discussed various aspects in terms of the basic physics, the configuration, and different modulation schemes of Electro optic devices. And now we will discuss another very promising aspect that is this Acousto optic Effect, the light matter interaction through acoustic waves in the host of material medium.

The Acousto optic Effect it basically consists of the interaction of the acoustic wave with the light wave through a medium where the medium will be deformed by the acoustic wave which is traveling through it. We know that when there is an acoustic wave, it creates a compression and rare refraction in the medium and the places where which is periodic and periodic with the frequency of the acoustic wave.

(Refer Slide Time: 01:28)

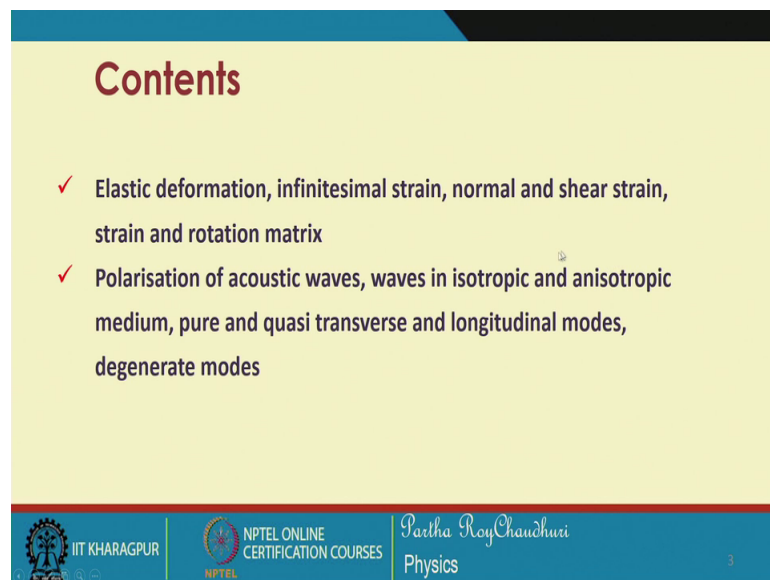

And the places where it is compressed and the places where it is rarefied, this the compression and rarefaction zones the material undergoes deformation up to different types. But this is a phenomenon which is which should happen even when there is a static strain if there is a force on a medium then the medium the bulk of the medium will

undergo some deformation, and this deformation will create in turns some strain. The strain will be inducing will be creating some changes in the optical properties in terms of the permittivity and the refractive indices of the material.

So, we do we will discuss this Acousto optic Effect initially with the elastic deformation which is the foundation to understand how this interaction takes place. We will study this elastic deformation in terms of the infinitesimal strain, the strain we will see that it is composed of normal strain and shear strain. Then there will be a strain and rotation matrix, which is there in the case of a deformation of any material medium. Then we will pick up this polarization optics a polarization of the acoustic waves.

(Refer Slide Time: 03:13)

Contents

- ✓ Elastic deformation, infinitesimal strain, normal and shear strain, strain and rotation matrix
- ✓ Polarisation of acoustic waves, waves in isotropic and anisotropic medium, pure and quasi transverse and longitudinal modes, degenerate modes

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri
Physics

Then the acoustic waves in an isotropic and anisotropic medium, pure and quasi transverse and longitudinal modes and the degenerate modes. So, first is to understand this elastic deformation.

(Refer Slide Time: 03:30)

Photo-elastic and acousto-optic

- ✓ Any elastic deformation and corresponding mechanical strain modifies the optical properties of a medium, be the medium an isotropic or an anisotropic **Photo-elastic effect**
- ✓ The elastic deformation producing strain by an acoustic wave is periodic in time and position in the medium
- ✓ The periodic deformation forms a periodic RI grating, stationary or travelling depending on the nature of wave **Acousto-optic effect**
A light wave passing through will be diffracted

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri
Physics

So, any elastic deformation and corresponding mechanical strain modifies the optical properties of a medium. This strain this deformation which could be fixed or which could be time varying, will create a strain in the medium. Whether the medium is isotropic and isotropic because of the strain, there will be change in the optical properties. This fact is the photo elastic effect. That is the modification of the optical properties as a result of the elastic deformation.

Now, when this elastic deformation that produce a strain, it could happen by a travelling acoustic wave, as the wave travels through the medium, there will be a periodic compression and rarefaction in the medium. That means, there will be a periodic deformation in the medium and because of the periodic deformation, there will be a periodic strain in the medium through which this acoustic wave is traveling because of this periodic strain, there will be periodic changes in the permittivity properties of the medium, which will be manifested in terms of the changes in the periodic changes in the refractive indices at the medium, which will result in a periodic refractive index grating.

That means, when an acoustic wave is travelling through a medium because of the dynamic photo elastic property, there will be periodic deformation, periodic strain, and periodic changes in the permittivity, periodic changes in the refractive indices, and therefore, there will be a formation of periodic grating as long as the acoustic wave is traveling through the medium.

Now, if a light wave is passing through such a medium, this wave we will see a dynamic periodic refractive index grating and as a result this light wave will be diffracted. This effect we will call this Acousto optic effect. That is the changes in the optical properties by an acoustic wave traveling through a medium, whether the medium is isotropic or anisotropic, this effect is always there, we will study the effect in the case of isotropic medium and anisotropic medium and in terms of various configurations of the acoustic wave through the medium. Whether it is a longitudinal wave or it is a shear wave we will study those cases.

But, by now we realize that it is important to understand the elastic deformation and how they are connected to the changes in the optical properties through a change in the permittivity of the medium periodic change in the permittivity of the medium when it is associated with an acoustic wave with a mechanical wave traveling through the medium. But otherwise for a static deformation, we will see how this deformation is related to strain and how the strain is related to the modification of the permittivity properties.

(Refer Slide Time: 07:17)

Elastic deformation

Coordinate of P : r^0

Coordinate of Q : $r^0 + dr^0$

Coordinate of P' : $r' = r^0 + u(r^0)$

Coordinate of Q' : $(r^0 + dr^0) + u(r^0 + dr^0)$

Separation P'-Q' :

$$dr' = (r^0 + dr^0) + u(r^0 + dr^0) - [r^0 + u(r^0)] \longrightarrow (1)$$

IIT KHARAGPUR

NPTEL ONLINE
CERTIFICATION COURSES

Partha RoyChaudhuri
Physics

So, elastic deformation let us first consider the deformation of an element within the volume of a medium. Let us suppose that, this is the original undeformed state of an element there are two points P and Q whose coordinates with respect to this lab frame is given by this r^0 and $r^0 + dr^0$. Now under deformation it moves to this place this is the deformed element where the point P has moved to P dash and the point Q has moved

to Q dash and the resulting separation is now dr' . So, this is the original element and this is the deformed element.

Now let us see that this coordinate of P dash is now $r^0 + u(r^0)$ a function of u ; u a function of r^0 whereas, the coordinate of Q dash is originally to $r^0 + dr^0$. So, u as a function of $r^0 + dr^0$ will be the new position characterized by this position. So, the deformed separation between these two points the original separation between P and Q was dr^0 , but the separation under deformation is dr' which is just the difference of these two.

So, we can write $r^0 + dr^0$; then minus of this quantity. So, therefore, we can write this equation we can write this equation because this u of $r^0 + dr^0$ minus u of r^0 . So, that they will cancel these two will cancel and this will be the you know Q dash minus P dash if you do you will obtain this equation, which is to define the separation between P dash and Q dash the deformed separation the separation between the points under deformation.

(Refer Slide Time: 09:37)

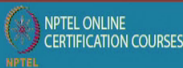

displacement

$$dr' = (r^0 + dr^0) + u(r^0 + dr^0) - [r^0 + u(r^0)]$$

We'll use Taylor expansion for $u(r^0 + dr^0)$:

$$u(r^0 + dr^0) = u(r^0) + \left. \frac{\partial u}{\partial x_1} \right|_{r^0} dx_1 + \left. \frac{\partial u}{\partial x_2} \right|_{r^0} dx_2 + \left. \frac{\partial u}{\partial x_3} \right|_{r^0} dx_3 + \text{other } |dr^0|^2$$

$$dr^0 = dr^0(dx_1, dx_2, dx_3)$$

So, dr' that separation is equal to this we will use this Taylor expansion of this. Now, these two terms we will be cancelled. So, $u(r^0 + dr^0)$ can be expanded in the Taylor series. So, if you written up to only three terms up to dx^3 . We can write this dr^0 as a function of dx_1, dx_2, dx_3 . Then we can expand this in this form. This dr^0 if we write as a function of dx_1, dx_2 , and dx_3 these coordinates we can expand in this from.

(Refer Slide Time: 10:22)

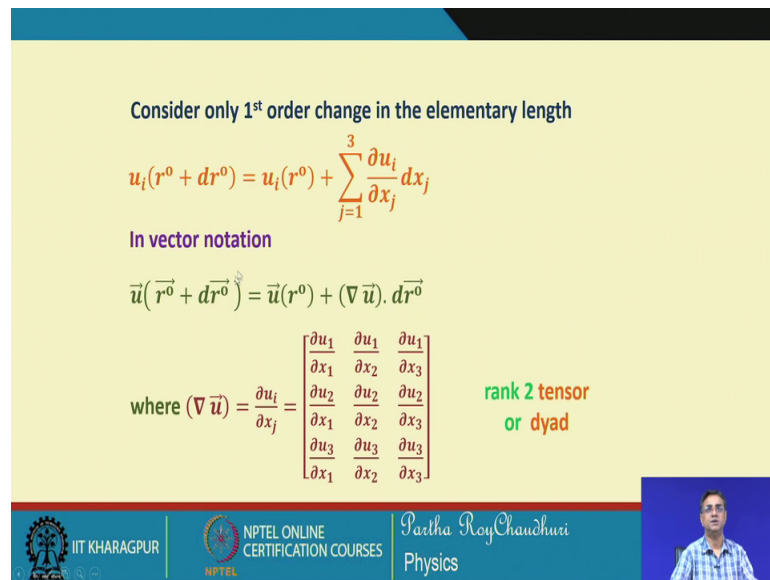

Consider only 1st order change in the elementary length

$$u_i(r^0 + dr^0) = u_i(r^0) + \sum_{j=1}^3 \frac{\partial u_i}{\partial x_j} dx_j$$

In vector notation

$$\vec{u}(r^0 + dr^0) = \vec{u}(r^0) + (\nabla \vec{u}) \cdot dr^0$$

where $(\nabla \vec{u}) = \frac{\partial u_i}{\partial x_j} = \begin{bmatrix} \frac{\partial u_1}{\partial x_1} & \frac{\partial u_1}{\partial x_2} & \frac{\partial u_1}{\partial x_3} \\ \frac{\partial u_2}{\partial x_1} & \frac{\partial u_2}{\partial x_2} & \frac{\partial u_2}{\partial x_3} \\ \frac{\partial u_3}{\partial x_1} & \frac{\partial u_3}{\partial x_2} & \frac{\partial u_3}{\partial x_3} \end{bmatrix}$ rank 2 tensor or dyad

So, this expansion can be written in the compact form returning up to three terms that u of r^0 plus dr^0 equal to u at r^0 plus this and then some of these terms. In the vector notation we can write this connection as u at r^0 and then $\nabla u \cdot dr^0$ which where this ∇u we know that it is the displacement ∇u by ∇x_j . So, where i and j can take up values up to 1, 2, 3 and this gives you this matrix which is a tensor and at a tensor of rank 2 or is also a dyad.

So, this is the ∇u this quantity which is represented by this can look at the diagonal elements ∇u and deformation along the same direction deformation along the same direction. So, the force the strain that is along the applied stress applied force. So, we will see how it works. So, in the vicinity of P we are to find we want to find the separation the change in the length of the segment PQ .

(Refer Slide Time: 11:46)

In the vicinity of P we are to find
the change in the length of line segment $PQ = d\vec{r}^0$
when it becomes $P'Q' = d\vec{r}'$ under deformation

From (1): $dr' = (r^0 + dr^0) + u(r^0 + dr^0) - [r^0 + u(r^0)]$

$$dr' = (r^0 + dr^0) + u(r^0) + \frac{\partial u_i}{\partial x_j} dx_j - r^0 - u(r^0)$$

$$dr' = dr^0 + \frac{\partial u_i}{\partial x_j} dx_j$$

Partha RoyChaudhuri
Physics

So, we started with a length PQ and now under deformation it has gone to P dash and Q dash. So, now, you would like to know how much is the change that has that this PQ element has suffered when it has become P dash and Q dash.

So, P dash and Q dash P dash Q dash minus P Q will be the change. And now this dr dash can be represented as this we have seen. So, this is the effective element therefore, d r dash which can be written as this quantity which can be written as this d r 0 plus dui dj dx j this also we have seen here d u d r 0 this quantity ok.

(Refer Slide Time: 12:46)

Change in the length ΔPQ :

$$(dr' - dr^0)_i = \frac{\partial u_i}{\partial x_j} dx_j$$

Relative change in length :

$$\frac{dr' - dr^0}{dr^0} = \frac{\partial u_i}{\partial x_j} = \text{deformation}$$

Partha RoyChaudhuri
Physics

So, now that change in the length P Q that is P dash Q dash minus P Q will be dr dash minus dr 0 therefore, in a compact notation we can write that this is equal to du ui dj dx j. So, this is the change and the change per unit length we will define the strain. So, if we divide this by d xj. So, this change has occurred for a length for a length over a length of d xj. So, if I divide this by dx j like this then it gives you the deformation that is dui.

So, change in the length per unit length will be dui by dj which is the deformation. So, we arrive at this that we have a deformation which is del u i d del x j where i and j can take up 1, 2, 3 values which will give you all nine elements deformation y with respect to x x with respect to y, z with respect to x and so on.

(Refer Slide Time: 13:57)

$$\frac{\partial u_i}{\partial x_j} = \begin{pmatrix} \frac{\partial u_1}{\partial x_1} & \frac{\partial u_1}{\partial x_2} & \frac{\partial u_1}{\partial x_3} \\ \frac{\partial u_2}{\partial x_1} & \frac{\partial u_2}{\partial x_2} & \frac{\partial u_2}{\partial x_3} \\ \frac{\partial u_3}{\partial x_1} & \frac{\partial u_3}{\partial x_2} & \frac{\partial u_3}{\partial x_3} \end{pmatrix} = \begin{pmatrix} \frac{\partial u_1}{\partial x_1} & \frac{1}{2} \left(\frac{\partial u_1}{\partial x_2} + \frac{\partial u_2}{\partial x_1} \right) & \frac{1}{2} \left(\frac{\partial u_1}{\partial x_3} + \frac{\partial u_3}{\partial x_1} \right) \\ \frac{1}{2} \left(\frac{\partial u_1}{\partial x_2} + \frac{\partial u_2}{\partial x_1} \right) & \frac{\partial u_2}{\partial x_2} & \frac{1}{2} \left(\frac{\partial u_2}{\partial x_3} + \frac{\partial u_3}{\partial x_2} \right) \\ \frac{1}{2} \left(\frac{\partial u_1}{\partial x_3} + \frac{\partial u_3}{\partial x_1} \right) & \frac{1}{2} \left(\frac{\partial u_2}{\partial x_3} + \frac{\partial u_3}{\partial x_2} \right) & \frac{\partial u_3}{\partial x_3} \end{pmatrix} + \begin{pmatrix} 0 & \frac{1}{2} \left(\frac{\partial u_1}{\partial x_2} - \frac{\partial u_2}{\partial x_1} \right) & \frac{1}{2} \left(\frac{\partial u_1}{\partial x_3} - \frac{\partial u_3}{\partial x_1} \right) \\ \frac{1}{2} \left(\frac{\partial u_2}{\partial x_1} - \frac{\partial u_1}{\partial x_2} \right) & 0 & \frac{1}{2} \left(\frac{\partial u_2}{\partial x_3} - \frac{\partial u_3}{\partial x_2} \right) \\ \frac{1}{2} \left(\frac{\partial u_3}{\partial x_1} - \frac{\partial u_1}{\partial x_3} \right) & \frac{1}{2} \left(\frac{\partial u_3}{\partial x_2} - \frac{\partial u_2}{\partial x_3} \right) & 0 \end{pmatrix}$$

So, that can be put in this form del u 1 del x 1. So, this is the deformation tensor which can be written in the form of two matrices, I retain the diagonal elements as it is, but it can also be written in this form half of del u 1 del x 1 plus del u 1 and del x 2 again so, that sums of the two elements half of that twice we can write in this form.

So, these diagonal elements will be 0 in the case of the second (Refer Time: 14:32) matrix and if I write this off diagonal elements in this form. So, the sum of these two will be the same as it is will be the same as the off diagonal elements. And so we can write this deformation matrix as a sum of two matrixes and let us see what does this matrix indicate and what does this matrix represent?

(Refer Slide Time: 15:09)

$$\begin{pmatrix} \frac{\partial u_1}{\partial x_1} & \frac{1}{2} \left(\frac{\partial u_1}{\partial x_2} + \frac{\partial u_2}{\partial x_1} \right) & \frac{1}{2} \left(\frac{\partial u_1}{\partial x_3} + \frac{\partial u_3}{\partial x_1} \right) \\ \frac{1}{2} \left(\frac{\partial u_1}{\partial x_2} + \frac{\partial u_2}{\partial x_1} \right) & \frac{\partial u_2}{\partial x_2} & \frac{1}{2} \left(\frac{\partial u_2}{\partial x_3} + \frac{\partial u_3}{\partial x_2} \right) \\ \frac{1}{2} \left(\frac{\partial u_1}{\partial x_3} + \frac{\partial u_3}{\partial x_1} \right) & \frac{1}{2} \left(\frac{\partial u_2}{\partial x_3} + \frac{\partial u_3}{\partial x_2} \right) & \frac{\partial u_3}{\partial x_3} \end{pmatrix} = S_{ij} = \text{strain tensor}$$

$$\begin{pmatrix} 0 & \frac{1}{2} \left(\frac{\partial u_1}{\partial x_2} - \frac{\partial u_2}{\partial x_1} \right) & \frac{1}{2} \left(\frac{\partial u_1}{\partial x_3} - \frac{\partial u_3}{\partial x_1} \right) \\ \frac{1}{2} \left(\frac{\partial u_2}{\partial x_1} - \frac{\partial u_1}{\partial x_2} \right) & 0 & \frac{1}{2} \left(\frac{\partial u_2}{\partial x_3} - \frac{\partial u_3}{\partial x_2} \right) \\ \frac{1}{2} \left(\frac{\partial u_3}{\partial x_1} - \frac{\partial u_1}{\partial x_3} \right) & \frac{1}{2} \left(\frac{\partial u_3}{\partial x_2} - \frac{\partial u_2}{\partial x_3} \right) & 0 \end{pmatrix} = R_{ij} = \text{rotation tensor}$$

So, this is you can see that $\frac{\partial u_1}{\partial x_1}$ this will define the strain because if you apply if there is a change in the length in the same direction per unit length that will define the normal strain this will be the normal strain. Whereas, this quantity $\frac{\partial u_1}{\partial x_2} + \frac{\partial u_2}{\partial x_1}$ will define the shear strain.

So, first matrix this one will be the it corresponds to the strain tensor whereas, this one $\frac{\partial u_1}{\partial x_2} - \frac{\partial u_2}{\partial x_1}$ and so on will represent a rotation tensor. Therefore, we find that any deformation can be expressed as a combination as a sum of a strain tensor as well as a rotation tensor. We will try to understand, how these terms represent rotation and these terms represent strain?

(Refer Slide Time: 16:20)

Thus, the deformation $\frac{\partial u_i}{\partial x_j} = S_{ij} + R_{ij}$ consists of

- ✓ infinitesimal **strain tensor** (*symmetric*)
$$S_{ij} = \frac{1}{2} \left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \right)$$
- ✓ and **rotation tensor** (*antisymmetric*)
$$R_{ij} = \frac{1}{2} \left(\frac{\partial u_i}{\partial x_j} - \frac{\partial u_j}{\partial x_i} \right)$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri | Physics

So, any deformation is the sum of a strain tensor and a rotation tensor where this S_{ij} stands for infinitesimal strain. If i equal to j then we get the diagonal elements, we get the diagonal elements i and j as the same. So, this will represent the normal strain and if they are different then we get the shear strain that is this tangential strain which are represented by this off diagonal elements. And for this R_{ij} this will be a the elements of the rotation tensor. We will see that this is anti symmetric, because θ_x will be mine in the off diagonal positions it will be minus θ_x .

(Refer Slide Time: 17:10)

Thus, the deformation =
infinitesimal **strain tensor** (*symmetric*) + **rotation tensor** (*antisymmetric*)

$\frac{\partial u_i}{\partial x_j} = S_{ij} + R_{ij}$ $S_{ij} = \frac{1}{2} \left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \right)$ $R_{ij} = \frac{1}{2} \left(\frac{\partial u_i}{\partial x_j} - \frac{\partial u_j}{\partial x_i} \right)$

- ✓ The infinitesimal **strain tensor** has **6** independent components
 S_{11}, S_{22}, S_{33} (**normal/tensile strain**)
 S_{12}, S_{23}, S_{31} (**shear strain**)
- ✓ The **rotation tensor** has **3** independent components R_{12}, R_{23}, R_{31}

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri | Physics

So, the deformation can be expressed as this strain infinitesimal strain tensor and an infinitesimal rotation tensor and they are represented by these two tensors. These two matrices the infinitesimal strain tensor has six independent components; we have seen they have six independent components, out of them these three diagonal components. The three diagonal components S_{11} , S_{22} and S_{33} they are the normal and tensile strain it represents a strain along the same direction whereas, it represents the strain along the perpendicular directions 12, 23 and 31.

So, the strain in that tangential direction is represented by this off diagonal elements. For the case of rotation tensor R_{11} , R_{22} , R_{33} that is the diagonal elements are always 0, but there will be three independent components R_{12} , R_{23} and R_{31} , we will see they are anti symmetric in nature.

(Refer Slide Time: 18:20)

normal/ tensile strain

$$S_{11} = \frac{\partial u_1}{\partial x_1}; \quad S_{22} = \frac{\partial u_2}{\partial x_2}; \quad S_{33} = \frac{\partial u_3}{\partial x_3}$$

shear strain elements

$$S_{12} = S_{21} = \frac{1}{2} \left(\frac{\partial u_1}{\partial x_2} + \frac{\partial u_2}{\partial x_1} \right); \quad S_{23} = S_{32} = \frac{1}{2} \left(\frac{\partial u_2}{\partial x_3} + \frac{\partial u_3}{\partial x_2} \right); \quad S_{13} = S_{31} = \frac{1}{2} \left(\frac{\partial u_1}{\partial x_3} + \frac{\partial u_3}{\partial x_1} \right)$$

rotation tensor elements

$$R_{21} = \frac{1}{2} \left(\frac{\partial u_2}{\partial x_1} - \frac{\partial u_1}{\partial x_2} \right); \quad R_{31} = \frac{1}{2} \left(\frac{\partial u_3}{\partial x_1} - \frac{\partial u_1}{\partial x_3} \right); \quad R_{23} = \frac{1}{2} \left(\frac{\partial u_2}{\partial x_3} - \frac{\partial u_3}{\partial x_2} \right)$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri | Physics

So, these are the normal strain, these are the shear strain elements of the strain matrix for the rotation matrix these are the three independent elements, 21 12 31 13 23 32. So, these are the shear elements.

(Refer Slide Time: 18:38)

Rotation Matrix

A small red dot is centered on the slide.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri Physics

(Refer Slide Time: 18:40)

Rotation of a vector

Consider any vector $\vec{A}(x, y, z)$

If the vector $\vec{A}(x, y, z)$ rotates the rotation operation is mathematically taking the curl of $\vec{A}(x, y, z)$

vector $\vec{A}(x, y, z)$ has to be differentiable everywhere within the field

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri Physics

Now, let us understand how it represents the rotation matrix. To understand that let us consider any vector and the rotation operation is nothing, but taking the curl of this vector and the property that is required that this vector A has to be differentiable everywhere within the field where we are looking for the rotation.

(Refer Slide Time: 19:00)

Rotation of a vector

Consider rotation of a vector $\vec{A}(x, y, z)$

Fig. 1

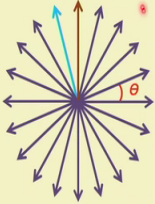

Fig. 2

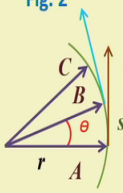

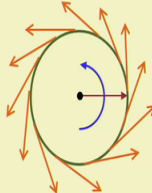

Fig. 3

 IIT KHARAGPUR  NPTEL ONLINE CERTIFICATION COURSES Partha RoyChaudhuri
Physics 

So, any rotation of a vector if we take this vector if we would to give a translation of this vector from here to here or from here to here, from here to here and from here to here the colors represent the positions, there parallel translation. So, being along the spoke this rotation of the vector is nothing, but being at the periphery of the rotation of the circumference the vectors like.

So, these two are identical situation these two are the same things. So, all the vectors can be picked up and placed at the periphery and they will look like this. So, this is the rotation of the vector a point A moves from A to B. A point A moves from A to B is nothing, but this vector this has undergone a change in it is position from here to here. A vector moves from this A to B and from B to C is nothing, but this vector has gone to this position and then internet has gone to this position. So, now we can change the, we can look at the change in the position of these two vectors.

(Refer Slide Time: 20:21)

Rotation of a vector

The point A moves from A to B
it results in the rotation of the radius vector \vec{r} by an angle θ
the particles displacement from A to B is s

Consider rotation of a rigid disc
the disc's rotation by θ , generates displacement vector $\vec{AB}, \vec{BC}, \dots$
For a complete rotation by 2π , any reference vector rotates through
all the stages as shown in **Figures**

One can give a translation of the vector from periphery to center
Translation of all vectors from **Fig. 3**, the new rotation visualization
is shown in **Fig. 1**

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri
Physics

So, it is like the rotation of a disc and as shown the stages in the figure, one can give a translation of the vector from the periphery to the center or from the center to the periphery as well. That gives you the new rotation visualization. This rotation this rotation of the vector can be thought of the rotation of the vector like this.

(Refer Slide Time: 20:47)

This rotation of \vec{A} by any amount θ can be
obtained by taking curl of \vec{A} as

$$\nabla \times \vec{A} = 2\vec{\theta}$$

Take example:
we have displacement: $\vec{s} = \vec{\theta} \times \vec{r}$
and rotation of \vec{v} is $\nabla \times \vec{s} = \nabla \times (\vec{\theta} \times \vec{r}) = 2\vec{\theta}$

And similarly:
the linear velocity: $\vec{v} = \vec{\omega} \times \vec{r}$
and rotation of \vec{v} is $\nabla \times \vec{v} = \nabla \times \vec{\omega} \times \vec{r} = 2\vec{\omega}$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri
Physics

So, therefore, this rotation of A by any amount θ can be obtained by taking the curl of this. So, $\nabla \times A$ is equal to 2θ , this we know from the elementary differential calculus and with mechanics. Then let us take the example if we take A is equal to

displacement vector, then this will be connected with theta S equal to r cross theta cross r and del cross S will give you 2 theta. And similarly if you take this A as the velocity vector, then V equal to omega cross r, which will give you del cross V equal to twice omega. That means, if you take 2 to this side omega will be represented by half of del cross V. And likewise if we take theta on this side and this 2 to this side so half of del cross S will represent this theta. So, any rotation theta will be represented by half of this curl of this displacement vector. So, this is the point that that is connected to there I connected to the elements of the rotation matrix.

(Refer Slide Time: 21:58)

Rotation tensor

Now for the displacement case $\nabla \times \vec{S} = 2\vec{\theta} \rightarrow \frac{1}{2}(\nabla \times \vec{S}) = \vec{\theta}$

A rotation about x in yz plane by an amount θ_x

$$\theta_x = \frac{1}{2} \left(\frac{\partial S_z}{\partial y} - \frac{\partial S_y}{\partial z} \right)$$

Similarly about y in zx plane by an amount θ_y , and about z in xy plane by θ_z

$$\theta_y = \frac{1}{2} \left(\frac{\partial S_x}{\partial z} - \frac{\partial S_z}{\partial x} \right) \text{ and } \theta_z = \frac{1}{2} \left(\frac{\partial S_y}{\partial x} - \frac{\partial S_x}{\partial y} \right)$$

The rotation is thus represented by a tensor $R_{ij} = \frac{1}{2} \left(\frac{\partial S_i}{\partial x_j} - \frac{\partial S_j}{\partial x_i} \right)$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri | Physics

Therefore, half of del cross S is equal to theta. If I now write it component wise then the rotation about x in y z plane by an amount theta x can be represented by, look at this if I take the x component of theta. Then I will have to take the x component of this quantity which will be del S z del y minus del S y del z. So, this is your theta x, but if we take del S y del z minus this then this will represent minus theta x. Similarly, theta y is this the y component of this vector on either side will give me this quantity z component of this vector on either side will give me.

So, I have been able to see that this rotation theta x is nothing, but this displacement of the displacement components of the displacement vector along different directions and their differences. So, this therefore, this rotation tensor elements R ij can be written as half of del S i del xj. You can see that i and j can take up 1, 2, 3 these three values. So, it

correctly represents the rotation of this vector. Therefore these elements are the R_{ij} and R_{ji} .

(Refer Slide Time: 23:33)

Rotation tensor: antisymmetric

$$R_{ij} = \begin{bmatrix} 0 & R_{xy} & R_{xz} \\ -R_{yx} & 0 & R_{yz} \\ -R_{zx} & -R_{zy} & 0 \end{bmatrix} = \begin{bmatrix} 0 & \theta_z & \theta_y \\ -\theta_z & 0 & \theta_x \\ -\theta_y & -\theta_x & 0 \end{bmatrix}$$

antisymmetric because θ_x and $-\theta_x$ are oppositely directed

R_{ij} = a deformation by rotation
= apply a torque or unlike parallel force of equal magnitude

S_{ij} = a deformation by translation
= apply a force along a Cartesian axis

We have to just flip this minus this and as a result this R_{xy} and R_{yx} there not same there will be a minus sign there will be a minus sign R_{xz} and R_{zx} they are not same there will be a minus sign. Therefore this rotation matrix is always an anti symmetric matrix. So, this anti symmetric so if the R_{ij} a deformation by rotation to visualize that to obtain that one has to apply a torque or unlike parallel force of equal magnitude which will create a rotation. And a deformation that occurs by translation to get that one has to apply a force along the Cartesian axis.

So, a torque is required to create a rotation and a translation a linear force is to be applied along the Cartesian axis to get the. But in the case of deformation both the things are coming into play and any deformation is a sum of these two things that is the strain and the rotation, which could be represented as the sum of the two tensors the strain tensor and the rotation tensor.

Acoustic waves

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri
Physics

And now we will see the deformation that is induced that is created in a material medium when the acoustic wave is traveling through it.

(Refer Slide Time: 25:00).

Light scattering by acoustic wave

Light scattering by acoustic wave

- ✓ First investigated by Brillouin : Brillouin Scattering
- ✓ Acoustic frequencies involved : **ULTRASONIC** and **HYPERSONIC**

↓
waves caused by thermal excitation in the medium

The study of acousto-optic effect

- ✓ Ultrasonic waves are used : frequency ~ 100 - few GHz

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri
Physics

So, this was first observed light scattering by acoustic wave by Brillouin and that is Brillouin scattering and acoustic frequencies involved ultrasonic and hypersonic waves. That is caused by thermal excitation in the medium. The study of acousto optic effect, is usually by ultrasonic waves are used within the frequency of 100 hertz to a few Gigahertz. So, this is the range of study of this acousto-optic effect.

Elastic waves in mater

For a given direction of propagation \vec{r} in a medium consider a **travelling plane** acoustic wave given by

$$u(\vec{r}, t) = U \cos(\vec{k} \cdot \vec{r} - \Omega t)$$

A **standing plane** acoustic wave is the superposition of two such counter-propagating travelling waves having **same amplitude, wavelength and frequency**

$$u(\vec{r}, t) = U \cos(\vec{k} \cdot \vec{r}) \cos \Omega t$$

The slide footer contains the IIT Kharagpur logo, NPTEL Online Certification Courses logo, and the name Partha Roy Chaudhuri, Physics. A small video inset shows a man in a blue shirt.

Now, elastic waves in matter for a given direction of propagation r in a medium any plane wave traveling plane acoustic wave can be represented by this. We have seen that this represents the phase of the wave, which is a plane wave front $k \cdot r$ minus ωt ; this capital ω is the frequency of the acoustic wave. This should be capital k in the case of acoustic wave if we want to differentiate from the electromagnetic waves capital k which will be the propagation vector U is the amplitude of the acoustic wave.

So, a standing acoustic wave is the superposition of two such forward propagating and backward propagating acoustic waves of the same amplitude. Then we get a standing wave which is also used to create a standing static type of deformation in the medium, which is also used as a fixed grating static grating in a medium. When we will see that if we allow the acoustic wave to be reflected back into the same medium in the same direction the superposition will create a standing wave and the position where it is compressed and the position where it is rarefied that will remain fixed with time with position, but not with time so, that will give rise to a static grating. So, this standing wave is also equally important standing acoustic wave to form a static refractive index grating.

Elastic waves in mater

For any given direction of propagation of an acoustic wave in a medium, there are three orthogonal normal modes of

Polarisation

If one mode is polarised along the propagation direction \vec{K} the polarisation of other two modes are perpendicular to \vec{K}

Acoustic wave

Polarised along the direction of \vec{K} is a longitudinal wave

Polarised perpendicular to \vec{K} is a transverse/shear wave

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri Physics

Now this looking at the elastic waves this property in the matter, there are three orthogonal modes of elastic waves in a in material medium. The polarization is one mode is polarized along the propagation direction that is what is called the longitudinal parallel polarization mode. The polarization of the other two modes are perpendicular to the direction of propagation K .

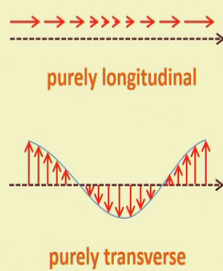

So, when there is an acoustic wave this could lead to a polarization that is along the direction of K and that is what is called the longitudinal wave. And when the polarization that is the medium particles the mechanical vibration of the particles occurs in the direction perpendicular direction to the direction of propagation K that is called the shear wave. And this shear wave we will be resulting that shear strain longitudinal wave will result in the longitudinal the normal strain that is the usual strain.

(Refer Slide Time: 28:15)

Elastic waves in mater

In an isotropic medium and cubic crystals:
Normal modes-
1 purely longitudinal
2 purely transverse

In anisotropic crystals other than triclinic:
If the wave travels along the crystal axis
(of 2-, 3-, 4-, 6 fold symmetry)
Normal modes-
1 purely longitudinal
2 purely transverse

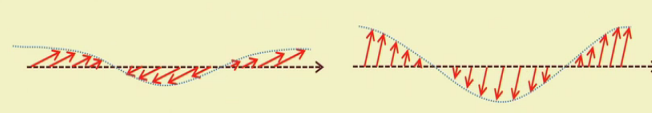

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri Physics

So, in anisotropic medium and cubic crystals this normal mode; one is purely longitudinal mode. You can see the medium will be compressed and rarified along the longitudinal direction; you can see the lengths of the vectors representing the compression and rarefaction in the medium. So, 1 purely longitudinal mode and there could be 2 purely transverse modes. So, this could be let us suppose this is directed along x, then there could be y polarization and there could be z polarization as well. So, there are two tangential modes to two transverse modes these two modes are degenerate they are identical.

(Refer Slide Time: 28:53)

Elastic waves in mater

In anisotropic crystals :
In general polarisations may not be parallel or perpendicular to \vec{K}
Such modes-
quasi longitudinal : polarisation direction close to \vec{K}
quasi transverse : polarisation perpendicular to \vec{K}

quasi longitudinal quasi transverse

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri Physics

So, in anisotropic medium anisotropic medium; however, in general the polarizations may not be parallel or perpendicular to \vec{K} . In general it may be that the it all depends on the material properties. So, it is very close to close to longitudinal modes that is why it is called the quasi longitudinal mode and whereas, this one is more inclined to the transverse tangential polarization. So, this is why it is called quasi transverse quasi transverse polarization.

(Refer Slide Time: 29:29)

At a given acoustic frequency in a given medium:
values of $v, \lambda, |\vec{K}|$ depend on directions of \vec{K} and polarisation

In isotropic medium
two transverse modes- degenerate, travels with same velocity
but transverse modes - not degenerate with longitudinal one

In a cubic crystal
Wave propagating along certain directions (1,0,0) and (1,1,1)
two transverse modes- degenerate, travels with same velocity

In anisotropic crystal
All three modes are in general non-degenerate and are distinct

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri
Physics

So, this again can have two polarizations whereas, this is the one possible polarization longitudinal mode.

So, at a given acoustic frequency in a medium the values of V , the velocity of the medium the periodicity and the propagation vector the depend on the direction of \vec{K} and the say all they put together they decide this polarization. So, in anisotropic medium you have two transverse modes two of them are, these two transverse mode are degenerate travel with the same velocity, but transverse modes are not degenerate with the longitudinal modes so they are different from the longitudinal mode. In a cubic crystal the wave propagating along certain directions defined by this direction or by 1,1,1 plane making an equaling inclination will all the three coordinate axis the two transverse modes are degenerate travel with the same velocity.

In anisotropic crystal all three modes are in general non degenerate and are distinct. In general if this is true for an isotropic medium because of the natural anisotropy of the

medium. So, by this discussion we try to understand that when an acoustic wave travels through a medium, it deforms the medium and this deformation will be decided by the polarization of the acoustic wave. It can have longitudinal polarization, it can have the transverse polarization, transverse polarization can have two degenerate modes.

So, these are all going to deform the medium periodically and as a result of that there will be a periodic changes in the mechanical properties, the strain. And as a result there will be a periodic changes in the permittivity and refractive index properties. We will discuss each of the cases in details and try to understand that different configurations of this longitudinal modes, transverse modes, x polarized modes, y polarized modes; in the case of isotropic material medium, in the case of an isotropic medium.

How they are going to change the permittivity properties? Periodic permittivity properties in the medium as long as that particular acoustic wave is existing in the medium we will try to understand, and then we will apply those deformation, those changes in the periodic refractive index properties to define the various modulation scheme and various devices.

(Refer Slide Time: 32:23)

----- Summary of discussion -----

- ✓ Elastic deformation, infinitesimal strain, normal and shear strain, strain and rotation matrix
- ✓ Polarisation of acoustic waves, waves in isotropic and anisotropic medium, pure and quasi transverse and longitudinal modes, degenerate modes

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha Roy Chaudhuri
Physics

So, by this discussion we try to understand this basic elastic deformation, the mechanical deformation properties. In terms of the infinitesimal strain which this strain is again consists of this normal strain and shear strain. If the displacement we estimate along the

change of the length along the same line same direction, then it is a normal strain. And if it is estimated in the along the perpendicular direction you apply a force along this direction and there is a change in a perpendicular direction. This all we know with all details that this is your shear strain.

So, both of these are going to constitute this mechanical strain. Whereas, the rotation matrix these two strain and rotation matrix these two put together defines the elastic deformation. Then we discuss this polarisation of acoustic waves, there are two different polarisation modes longitudinal modes and transverse modes. These transverse modes are also composed of two degenerate orthogonal modes; there could be pure and quasi transverse and longitudinal modes. We will continue with these acoustic waves in the medium.

Thank you.
