Lecture – 05
Maxwell's equations and electromagnetic waves (Contd.)

Today we will discuss the propagation of electromagnetic waves and energy flow this is a very interesting topic and will be useful throughout our discussion Energy Flow and Poynting Theorem.

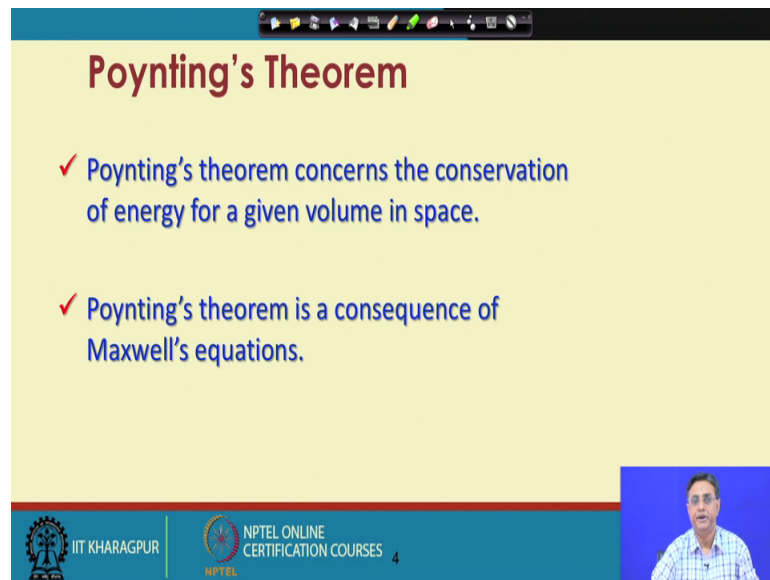

(Refer Slide Time: 00:33)

So, we will be discussing under the following heads that energy transport in electromagnetic waves in a certain volume of the space through which the electromagnetic waves are travelling, how the energy is entering and how much of the energy is leaving out of that space that will clearly quantify will try to understand how the loss is taking place within that volume.

Then in the process we will work out the Poynting vector and the Poynting theorem look at each of the terms of the Poynting theorem. Followed by this we will take two example cases, the energy transport in a dielectric medium and we will also considered the transport of energy in a conducting medium.

(Refer Slide Time: 01:27)

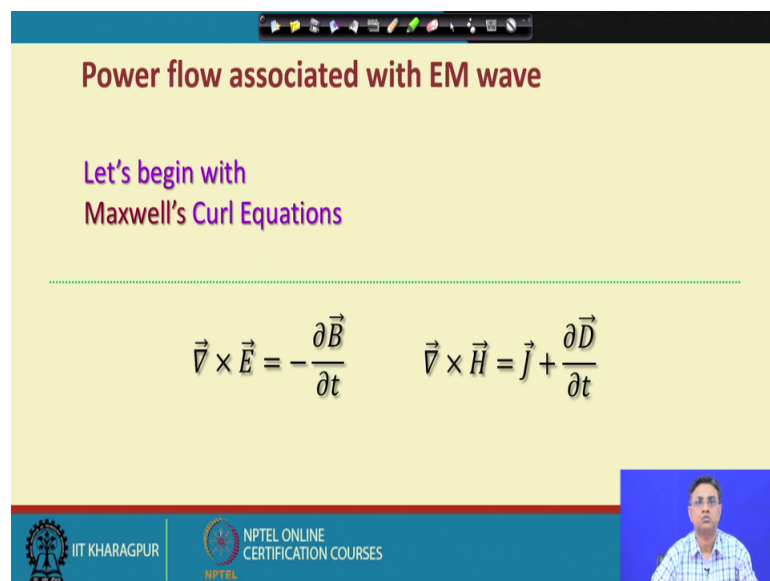

Poynting's Theorem

- ✓ Poynting's theorem concerns the conservation of energy for a given volume in space.
- ✓ Poynting's theorem is a consequence of Maxwell's equations.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES 4

So, Poynting theorem, Poynting theorem basically concerns the conservation of energy for a given volume in space. As I have mentioned that when the electromagnetic waves are travelling through certain region of space within the volume the energy, how much part of the energy is lost and how much part of the energy is flowing out; we will correlate these two things and this will be described through this Poynting theorem which is actually a consequence of the Maxwell's equation and we will start with the Maxwell's equation to arrive at the conclusion.

(Refer Slide Time: 02:12)

Power flow associated with EM wave

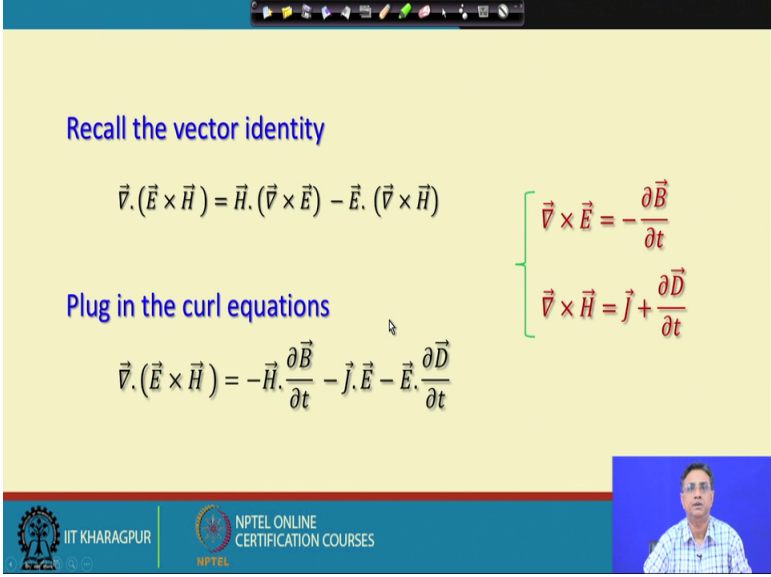

Let's begin with
Maxwell's Curl Equations

$$\vec{\nabla} \times \vec{E} = -\frac{\partial \vec{B}}{\partial t} \quad \vec{\nabla} \times \vec{H} = \vec{J} + \frac{\partial \vec{D}}{\partial t}$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, let us begin with the Maxwell's curl equations, we have these two famous curls equations that $\nabla \times \vec{E}$ equal to minus $\nabla \vec{B}$ del t and $\nabla \times \vec{H}$ equal to \vec{j} plus $\nabla \vec{D}$ del t where \vec{B} is the magnetic field and \vec{D} is the displacement current \vec{j} is the induction current.

(Refer Slide Time: 02:46)

Recall the vector identity

$$\vec{\nabla} \cdot (\vec{E} \times \vec{H}) = \vec{H} \cdot (\vec{\nabla} \times \vec{E}) - \vec{E} \cdot (\vec{\nabla} \times \vec{H})$$

Plug in the curl equations

$$\vec{\nabla} \cdot (\vec{E} \times \vec{H}) = -\vec{H} \cdot \frac{\partial \vec{B}}{\partial t} - \vec{j} \cdot \vec{E} - \vec{E} \cdot \frac{\partial \vec{D}}{\partial t}$$

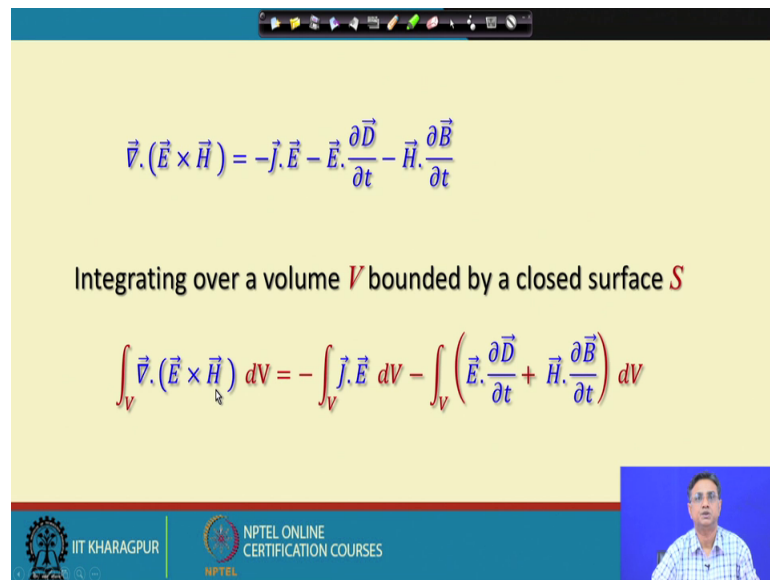

$$\left\{ \begin{array}{l} \vec{\nabla} \times \vec{E} = -\frac{\partial \vec{B}}{\partial t} \\ \vec{\nabla} \times \vec{H} = \vec{j} + \frac{\partial \vec{D}}{\partial t} \end{array} \right.$$

IIT KHARAGPUR NPTEL ONLINE CERTIFICATION COURSES

So, starting with these two equations, we will organize the Poynting vector; let us recall that the vector identity that is, $\nabla \cdot (\vec{E} \times \vec{H})$. This left hand side can be written in the form that $\vec{H} \cdot \nabla \times \vec{E}$ minus $\vec{E} \cdot \nabla \times \vec{H}$.

So, if we plug in the curl equations for this $\nabla \times \vec{E}$ and for $\nabla \times \vec{H}$ from here that is $\nabla \times \vec{E}$ equal to we will substitute minus $\nabla \vec{B}$ del t and for $\nabla \times \vec{H}$ will substitute \vec{j} plus $\nabla \vec{D}$ del t. If you do that this quantity $\vec{H} \cdot \nabla \times \vec{E}$ becomes $\vec{H} \cdot \nabla \vec{B}$ del t, because $\nabla \times \vec{E}$ is now replaced by minus of $\nabla \vec{B}$ del t and for $\nabla \times \vec{H}$ if I substitute this quantity \vec{j} plus $\nabla \vec{D}$ del t, then it becomes minus $\vec{j} \cdot \vec{E}$ minus $\vec{E} \cdot \nabla \vec{D}$ del t. So, this is the equation which involves the $\vec{E} \times \vec{H}$ divergence of that.

(Refer Slide Time: 04:18)

The slide displays the following vector equation:

$$\vec{\nabla} \cdot (\vec{E} \times \vec{H}) = -\vec{j} \cdot \vec{E} - \vec{E} \cdot \frac{\partial \vec{D}}{\partial t} - \vec{H} \cdot \frac{\partial \vec{B}}{\partial t}$$

Integrating over a volume V bounded by a closed surface S

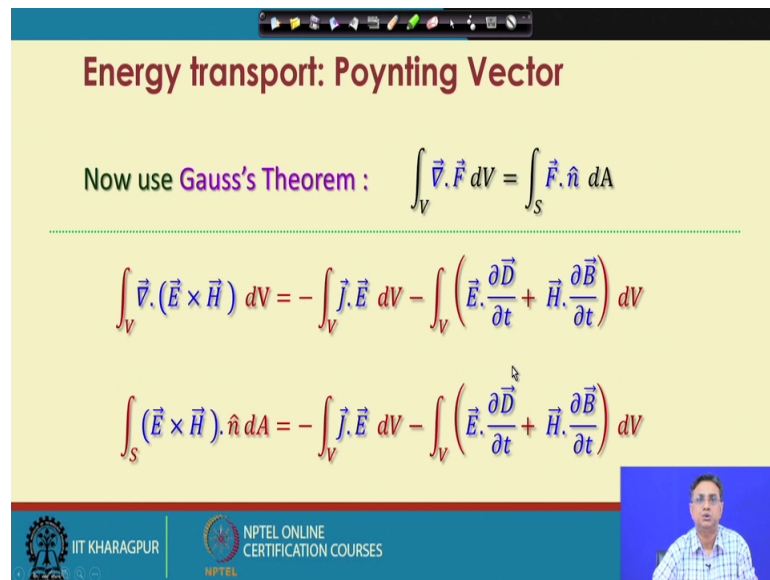

$$\int_V \vec{\nabla} \cdot (\vec{E} \times \vec{H}) dV = - \int_V \vec{j} \cdot \vec{E} dV - \int_V \left(\vec{E} \cdot \frac{\partial \vec{D}}{\partial t} + \vec{H} \cdot \frac{\partial \vec{B}}{\partial t} \right) dV$$

The slide footer includes the IIT KHARAGPUR logo and the text "NPTEL ONLINE CERTIFICATION COURSES". A small video inset of a lecturer is visible in the bottom right corner.

So, let us look at this; $\nabla \cdot (\vec{E} \times \vec{H})$ minus $\vec{E} \cdot \frac{\partial \vec{D}}{\partial t}$ minus $\vec{H} \cdot \frac{\partial \vec{B}}{\partial t}$ equal to minus $\vec{j} \cdot \vec{E}$. We have just rearranged this equation in a fashion that, we have taken this quantity and this quantity together which is a like and this quantity we have placed separately. The reason is very clear that we want to look at these terms these two terms put together and also this term $\vec{j} \cdot \vec{E}$.

Now, let us consider a certain volume of space through which this electromagnetic wave is travelling and let us consider that the area bound surface area bound by this volume is S is a close surface. So, we can write this equation, if you take if integrate over this volume, we can write this equation $\nabla \cdot (\vec{E} \times \vec{H})$ dV is equal to minus $\vec{j} \cdot \vec{E}$ dV minus $\vec{E} \cdot \frac{\partial \vec{D}}{\partial t}$ plus $\vec{H} \cdot \frac{\partial \vec{B}}{\partial t}$.

(Refer Slide Time: 05:40)

Energy transport: Poynting Vector

Now use Gauss's Theorem : $\int_V \vec{\nabla} \cdot \vec{F} dV = \int_S \vec{F} \cdot \hat{n} dA$

$$\int_V \vec{\nabla} \cdot (\vec{E} \times \vec{H}) dV = - \int_V \vec{j} \cdot \vec{E} dV - \int_V \left(\vec{E} \cdot \frac{\partial \vec{D}}{\partial t} + \vec{H} \cdot \frac{\partial \vec{B}}{\partial t} \right) dV$$

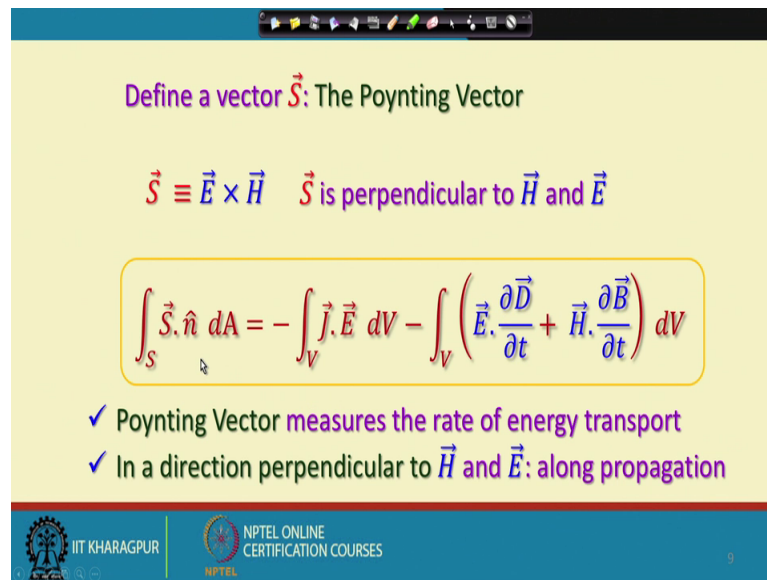

$$\int_S (\vec{E} \times \vec{H}) \cdot \hat{n} dA = - \int_V \vec{j} \cdot \vec{E} dV - \int_V \left(\vec{E} \cdot \frac{\partial \vec{D}}{\partial t} + \vec{H} \cdot \frac{\partial \vec{B}}{\partial t} \right) dV$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Now, look at these two terms we will use Gauss's theorem to see what is meant by this quantity $\vec{\nabla} \cdot (\vec{E} \times \vec{H})$. So, Gauss's theorem states that it relates the volume integral to a surface integral for a vector field \vec{H} the divergence of this vector field over a volume is equal to the closed surface integral of the vector field.

So, by replacing this \vec{F} by $\vec{E} \times \vec{H}$ that is if we substitute for \vec{F} this $\vec{E} \times \vec{H}$, then we can rewrite this equation $\int_V \vec{\nabla} \cdot (\vec{E} \times \vec{H}) dV$ equal to the right hand side which you have seen as it is. Now if I apply this Gauss's theorem, I can write this equation as surface integral of $\vec{E} \times \vec{H}$ that is $\int_S (\vec{E} \times \vec{H}) \cdot \hat{n} dA$ integral of that will be equal to the right hand side.

(Refer Slide Time: 06:58)

Define a vector \vec{S} : The Poynting Vector

$\vec{S} \equiv \vec{E} \times \vec{H}$ \vec{S} is perpendicular to \vec{H} and \vec{E}

$$\int_S \vec{S} \cdot \hat{n} dA = - \int_V \vec{J} \cdot \vec{E} dV - \int_V \left(\vec{E} \cdot \frac{\partial \vec{D}}{\partial t} + \vec{H} \cdot \frac{\partial \vec{B}}{\partial t} \right) dV$$

- ✓ Poynting Vector measures the rate of energy transport
- ✓ In a direction perpendicular to \vec{H} and \vec{E} : along propagation

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Now, we will define the Poynting vector the Poynting vector is defined as the cross product of E field and the magnetic field. So, \vec{S} is equal to $\vec{E} \times \vec{H}$, you can see from this definition that \vec{S} is perpendicular to \vec{E} also \vec{S} is perpendicular to \vec{H} ; that means, this Poynting vector is a vector which is perpendicular to the plane containing the electric field and the magnetic field; that means, if this Poynting vector has to represent certain quantity, then the direction of that quantity will be perpendicular to the plane that contains the electric field and magnetic field and we know that electric and magnetic field they are also perpendicular to each other, as a result this \vec{S} , \vec{E} and \vec{H} they form a right handed set of vectors.

Now, if we replace this $\vec{E} \times \vec{H}$ by this quantity Poynting vector \vec{S} , then $\oint \vec{S} \cdot \hat{n} dA$ surface integral of that will be equal to the quantity which we have described before that is $\int \vec{J} \cdot \vec{E} dV$ minus $\int \vec{E} \cdot \frac{\partial \vec{D}}{\partial t} + \vec{H} \cdot \frac{\partial \vec{B}}{\partial t} dV$ volume integral of that. So, it tells you that the Poynting vector measures the rate of energy transport and the energy transport it happens in a direction which is perpendicular to both the magnetic field and electric field and; that means, it is along the direction of propagation direction. So, the propagation direction is the direction along which the energy transport takes place.

(Refer Slide Time: 09:03)

Recall that

Using the constitutive relations

Energy density associated with

Electric Field : $w_E = \frac{1}{2}(\vec{E} \cdot \vec{D}) = \frac{1}{2}\epsilon \cdot E^2$

Magnetic Field : $w_B = \frac{1}{2}(\vec{H} \cdot \vec{B}) = \frac{1}{2}\mu \cdot H^2$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | 10

Now, let us recall that using the constitutive relations, the energy density that is associated with the electric field is half $\vec{E} \cdot \vec{D}$ that is equal to half epsilon E square and the magnetic field energy density associated with the magnetic field is in the same way half $\vec{H} \cdot \vec{B}$ which is equal to half mu dot H mu into a H square.

(Refer Slide Time: 09:38)

Terms in Poynting's Theorem

energy density associated with electric and magnetic fields

$w_E = \frac{1}{2}(\vec{E} \cdot \vec{D})$

$w_B = \frac{1}{2}(\vec{H} \cdot \vec{B})$

$\vec{E} \cdot \frac{\partial \vec{D}}{\partial t} = \frac{1}{2}\epsilon \cdot \frac{\partial E^2}{\partial t} = \frac{1}{2} \frac{\partial}{\partial t}(\vec{E} \cdot \vec{D}) = \frac{\partial}{\partial t}(w_E)$

$\vec{H} \cdot \frac{\partial \vec{B}}{\partial t} = \frac{1}{2}\mu \cdot \frac{\partial H^2}{\partial t} = \frac{1}{2} \frac{\partial}{\partial t}(\vec{H} \cdot \vec{B}) = \frac{\partial}{\partial t}(w_B)$

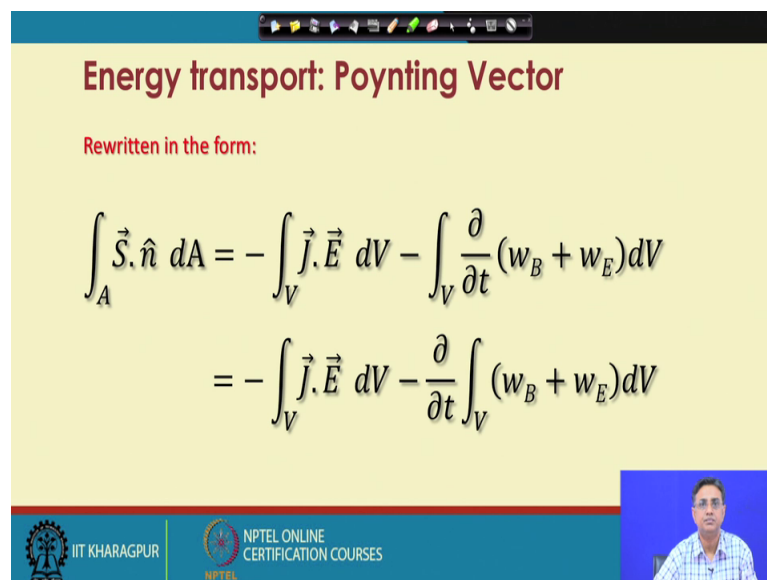

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | 11

So, if we use definition of the of the electric and magnetic field energy density, then we can write that $\vec{E} \cdot \text{del } \vec{D} \text{ del } t$ which is equal to half of epsilon is replacing this \vec{D} that is \vec{D} equal to $\epsilon \vec{E}$ into epsilon. So, half epsilon into $\text{del } E^2 \text{ del } t$ which can be rewritten

in this form half $\frac{d}{dt} \int_V \mathbf{E} \cdot \mathbf{D} dV$ which is equal to $\frac{d}{dt}$ of the energy density w_E electrical energy density.

So, we have used this electrical energy density here in place of this you can take half inside. So, it gives you this quantity and in the same way if we proceed, then for $\frac{d}{dt} \int_V \mathbf{H} \cdot \mathbf{B} dV$, we can write half $\mu_0 \frac{d}{dt} \int_V \mathbf{H}^2 dV$ which is equal to half of $\frac{d}{dt} \int_V \mathbf{H} \cdot \mathbf{B} dV$ and in turn this gives you $\frac{d}{dt} \int_V w_B dV$ which is the energy density associated with the magnetic field. Therefore, these two terms which are appearing in the equation can be replaced by the sum of these two terms; that means, we can represent this sum of these two terms is equal to $\frac{d}{dt} \int_V (w_B + w_E) dV$ of the sum of the energy density is associated with the electric and magnetic fields.

(Refer Slide Time: 11:23)

Energy transport: Poynting Vector

Rewritten in the form:

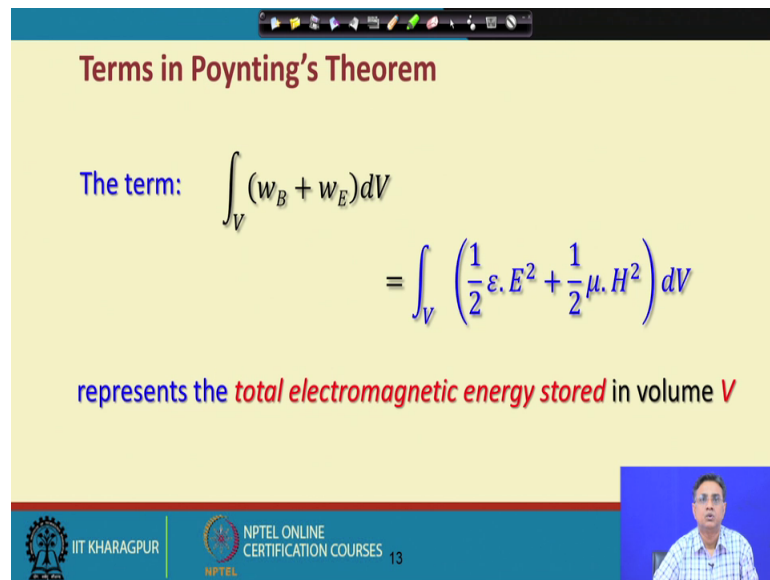

$$\int_A \vec{S} \cdot \hat{n} dA = - \int_V \vec{J} \cdot \vec{E} dV - \int_V \frac{\partial}{\partial t} (w_B + w_E) dV$$

$$= - \int_V \vec{J} \cdot \vec{E} dV - \frac{\partial}{\partial t} \int_V (w_B + w_E) dV$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, if we rewrite this equation that $\vec{S} \cdot \hat{n}$ this left hand side the Poynting vector surface integral of that will be equal to $\int_V \vec{J} \cdot \vec{E} dV$ and this quantity. Just now we have seen that $\frac{d}{dt} \int_V w_B dV$ and $\frac{d}{dt} \int_V w_E dV$ is the translated form of the individual variation of the electric and magnetic fields. So, we can write this equation if you take $\frac{d}{dt}$ outside the integral, then we can write that it represents the total energy, energy density associated with the magnetic field and electric field over this volume and $\frac{d}{dt}$ of that that is the rate of change.

(Refer Slide Time: 12:19)

Terms in Poynting's Theorem

The term:
$$\int_V (w_B + w_E) dV$$
$$= \int_V \left(\frac{1}{2} \epsilon \cdot E^2 + \frac{1}{2} \mu \cdot H^2 \right) dV$$

represents the **total electromagnetic energy stored** in volume **V**

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | 13

So, let us let us look at this term that that the energy density some of the energy density is for the magnetic field and for the electric field is equal to this just now we have seen. But because this is the total energy density with the electric field and magnetic field, so this quantity actually represents the total electromagnetic energy stored in the volume V.

So, total we have to magnetic energy in a volume V and if you take del del t of that that will represent the change in the total electromagnetic energy that is stored within that volume. If we place a minus sign before that it should definitely represent that this amount of energy will be the loss.

(Refer Slide Time: 13:09)

Terms in Poynting's Theorem

The term : $\int_S \vec{S} \cdot \hat{n} \, dA = \int_S (\vec{E} \times \vec{H}) \cdot \hat{n} \, dA$

represents the *flow of instantaneous power*
out of the volume *V* through the surface *S*

And if you look at this term that is $\vec{S} \cdot \hat{n} \, dA$ which is equal to this, this actually represents the instantaneous power flow of instantaneous power instantaneous power out of the volume V through the surface S .

(Refer Slide Time: 13:31)

Energy transport: Poynting Vector

Rewritten in the form:

$$\int_A \vec{S} \cdot \hat{n} \, dA = - \int_V \vec{j} \cdot \vec{E} \, dV - \int_V \frac{\partial}{\partial t} (w_B + w_E) dV$$

Total power flowing
out of a volume V

Dissipated power
in volume V

Total electromagnetic
energy change in volume V

or, $\vec{\nabla} \cdot \vec{S} + \frac{\partial}{\partial t} (w_B + w_E) = -\vec{j} \cdot \vec{E}$

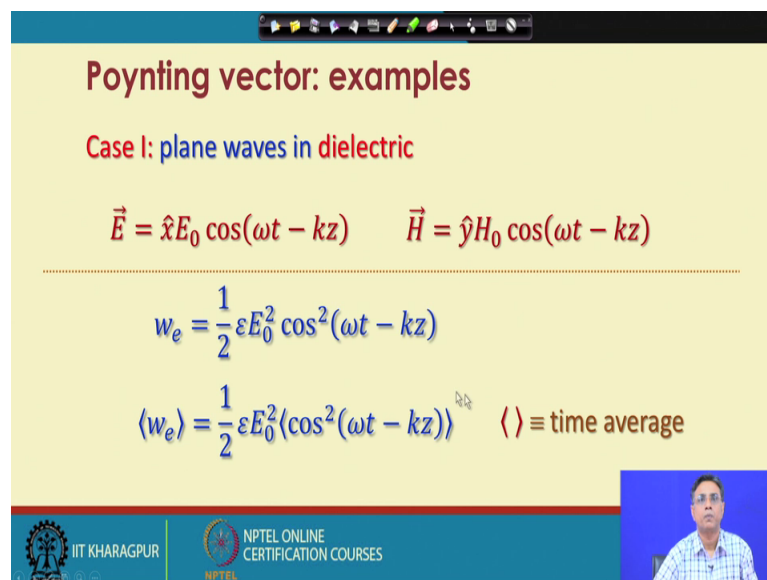

Now, again rewriting this equation in this form, this left hand side that is the term which contains the Poynting vector represents the total power flowing out of the volume V which is equal to the power in the volume dissipated power in the volume and also the total electromagnetic energy change in the volume. This is just now I have mentioned

that this quantity $\nabla \cdot (\mathbf{w}_B + \mathbf{w}_E)$ that is the energy densities of the electric field and the magnetic field integrated over the volume dV represents the total volume within that space, total energy stored within that space and if you take the time derivative of that it represents the change in that energy and since there is a minus sign, so it represents that the loss of the energy from that space.

So, if you look at this equation, the energy flow through that volume will be equal to the loss of the energy from that volume and the dissipated power within that volume. So, that is very consistent and it really represents the conservation of energy; $\nabla \cdot \mathbf{S}$ because this quantity we have called that power dissipation because $\nabla \cdot \mathbf{S}$ and this $\nabla \cdot \mathbf{B} \frac{d}{dt}$ the continuity equation is equal to minus $\mathbf{J} \cdot \mathbf{E}$.

(Refer Slide Time: 15:19)

Poynting vector: examples

Case I: plane waves in dielectric

$$\vec{E} = \hat{x}E_0 \cos(\omega t - kz) \quad \vec{H} = \hat{y}H_0 \cos(\omega t - kz)$$

$$w_e = \frac{1}{2} \epsilon E_0^2 \cos^2(\omega t - kz)$$

$$\langle w_e \rangle = \frac{1}{2} \epsilon E_0^2 \langle \cos^2(\omega t - kz) \rangle \quad \langle \rangle \equiv \text{time average}$$

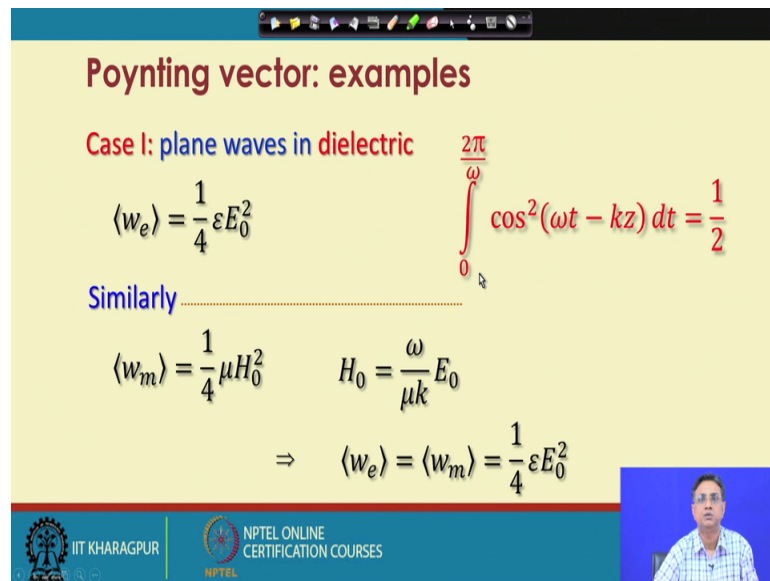

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, we will consider two different cases one is the dielectric and through which a plane wave propagating and how this Poynting vector measures the flow of energy and followed by that we will consider another situation when the electromagnetic wave is propagating in a conducting medium. So, in this case we can represent the electric field E as $x \cap E_0 \cos(\omega t - kz)$ as if the wave is propagating along the z direction, then the magnetic field can be written as this because electric field is x polarized and the magnetic field is y polarized.

So, the energy density associated with the electric field can be calculated as the integral of this, then half of $E_0^2 \cos^2(\omega t - kz)$. So, this quantity if I take the

time average time average of this, that is integral over a complete cycle; then we can write that the value of this will be because for 0 to twice pi by omega time that is t will give you the value half and you already have half. So, omega E the time average of the electrical energy density associated with electric field will be equal to one upon four E epsilon E naught square where E naught is the amplitude of the electric field.

(Refer Slide Time: 16:41)

Poynting vector: examples

Case I: plane waves in dielectric

$$\langle w_e \rangle = \frac{1}{4} \epsilon E_0^2$$

$$\int_0^{\frac{2\pi}{\omega}} \cos^2(\omega t - kz) dt = \frac{1}{2}$$

Similarly

$$\langle w_m \rangle = \frac{1}{4} \mu H_0^2 \quad H_0 = \frac{\omega}{\mu k} E_0$$

$$\Rightarrow \langle w_e \rangle = \langle w_m \rangle = \frac{1}{4} \epsilon E_0^2$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

In the same way if I consider the magnetic field; energy density associated with the magnetic field, then we can calculate to be equal to 1 upon 4 mu H 0 square where H 0 is the amplitude of the magnetic field. This we could arrive at using this relation H 0 equal to omega by mu into k into E 0. So, if you substitute this, we can see that the electrical energy density, the energy density associated with the electric field and that associated with the magnetic field the average value of that over a complete cycle will be the same that is 1 upon of 4 mu epsilon naught square.

(Refer Slide Time: 18:03)

Poynting vector: energy flow

$$\langle w \rangle = 2\langle w_e \rangle = \frac{1}{2} \epsilon E_0^2$$

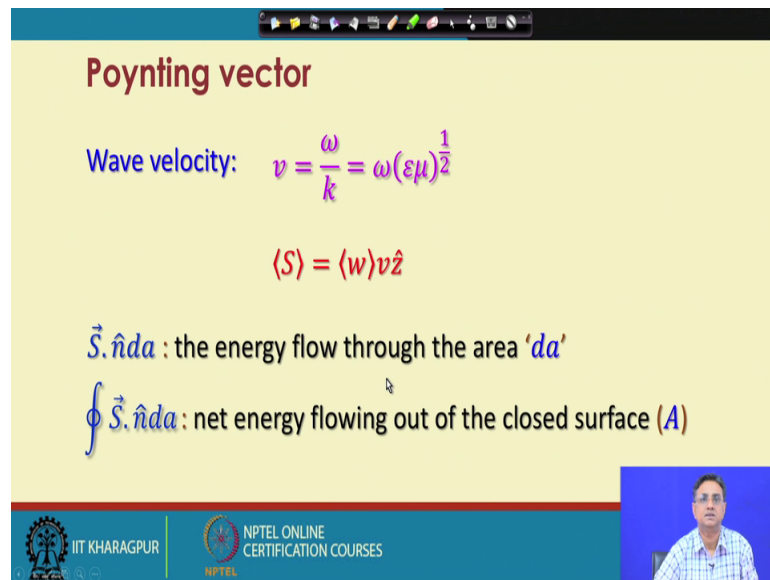

The Poynting vector

$$\vec{S} = \vec{E} \times \vec{H} = E_0 H_0 \cos^2(\omega t - kz) \hat{z}$$
$$\langle S \rangle = \frac{1}{2} \left(\frac{k}{\omega \mu} \right) E_0^2 \hat{z} = \frac{1}{2} \left(\frac{\epsilon}{\mu} \right)^{\frac{1}{2}} E_0^2 \hat{z}$$

The slide includes a video inset of a lecturer in the bottom right corner. The footer contains the IIT KHARAGPUR logo and the text 'NPTEL ONLINE CERTIFICATION COURSES'.

So, I mean known this fact, then we can write the total energy density average value of that which represents energy. So, will be equal to twice the contribution is both from the electric field and the magnetic field which will be equal to half $E E_0$ epsilon naught E_0 square which is again consistent with the with the our previous information that the Poynting vector S , there should be a mod S is equal to mod of E cross H which is equal to $E_0 H_0$ cosine square ωt minus z , since if you take mod then this z cap is not required. So, in that case the average value of the Poynting vector S will be equal to half of k by $\omega \mu$ and E_0 square z that will give you this value. So, we could so that the flow of energy which is given by the Poynting vector is equal to this. So, these two are the same equation.

(Refer Slide Time: 19:18)

Poynting vector

Wave velocity: $v = \frac{\omega}{k} = \omega(\epsilon\mu)^{\frac{1}{2}}$

$\langle S \rangle = \langle w \rangle v \hat{z}$

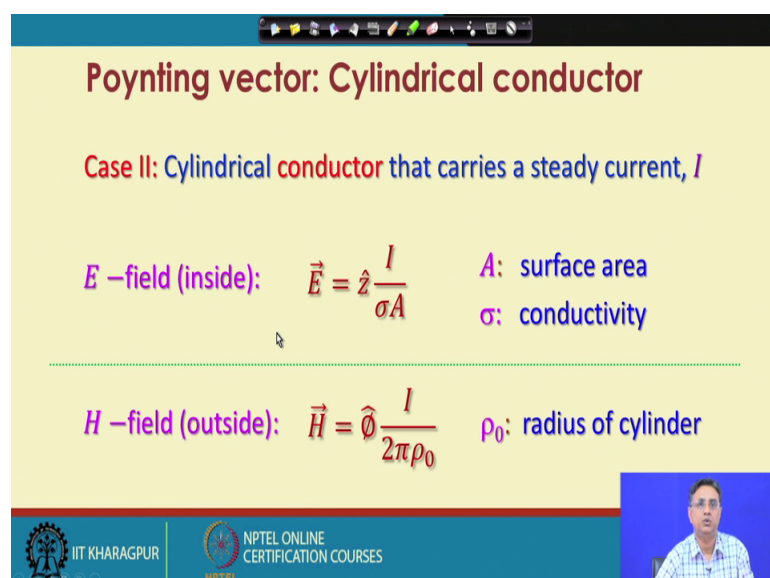

$\vec{S} \cdot \hat{n} da$: the energy flow through the area ' da '

$\oint \vec{S} \cdot \hat{n} da$: net energy flowing out of the closed surface (A)

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Now, since the wave velocity of an electromagnetic wave can be given by v equal to ω by k and k can be replaced by $\mu\epsilon$ naught to the power of half. So, we can write that the average value of the Poynting vector is equal to the average energy density into the velocity that means, the average energy that is associated with the both the electric and magnetic field and over a distance which is given by the velocity will be equal. So, a $\vec{S} \cdot \hat{n} da$ that is the energy flow through the area perpendicular to the area da is represented by this which will account for the net energy flowing out of the closed surface a .

(Refer Slide Time: 20:21)

Poynting vector: Cylindrical conductor

Case II: Cylindrical conductor that carries a steady current, I

E -field (inside): $\vec{E} = \hat{z} \frac{I}{\sigma A}$ A : surface area
 σ : conductivity

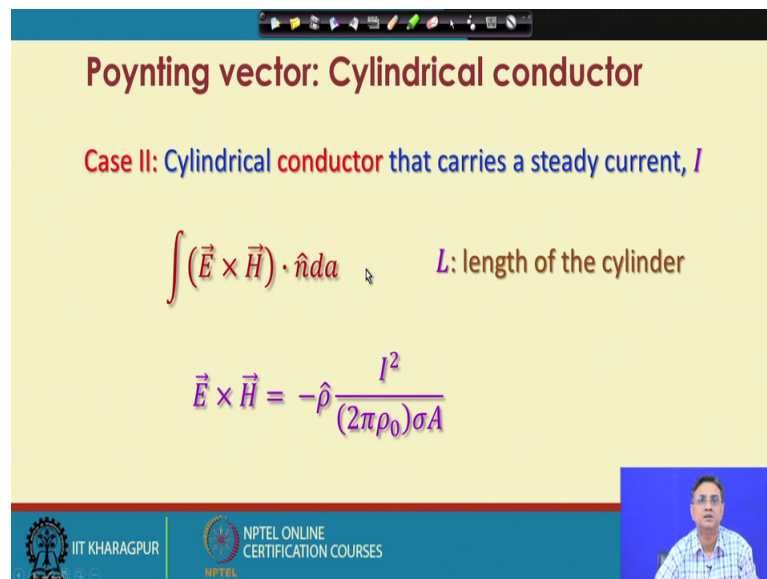

H -field (outside): $\vec{H} = \hat{\phi} \frac{I}{2\pi\rho_0}$ ρ_0 : radius of cylinder

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Now, we will consider another interesting case where we will see the Poynting vector through a cylindrical conductor that carries a steady current, I . Now the electric field inside this conductor is given by this E equal to z cap I by σ into A , this is because this Ohms law if you write J into σ is equal to E . So, σ into E is equal to z into J .

So, in place of J we have written I by A where A is a surface area and σ is a conductivity of the conductor and the magnetic field outside this conductor can be represented by H equal to ϕI by twice π ρ . So, z and ϕ they are mutually orthogonal z is along the axis of the conductor ϕ is in the azimuth. So, if you take E cross H that should represent a direction, which will be perpendicular to z and ϕ and in the outward direction. So, this will be evidently along the ρ direction that is the radius vector direction of the cylindrical coordinate system representing the cylindrical conductor.

(Refer Slide Time: 21:58)

Poynting vector: Cylindrical conductor

Case II: Cylindrical conductor that carries a steady current, I

$$\int (\vec{E} \times \vec{H}) \cdot \hat{n} da \quad L: \text{length of the cylinder}$$

$$\vec{E} \times \vec{H} = -\hat{\rho} \frac{I^2}{(2\pi\rho_0)\sigma A}$$

The slide includes logos for IIT KHARAGPUR and NPTEL ONLINE CERTIFICATION COURSES at the bottom. A small video inset shows a man speaking.

So, let us see that for the cylindrical conductor that carries a current I , we can write the Poynting vector in this way E cross H dot \hat{n} da where we consider a certain length L of the cylinder.

(Refer Slide Time: 22:18)

Poynting vector: Cylindrical conductor

Case II: Cylindrical conductor that carries a steady current, I

E -field (inside): $\vec{E} = \hat{z} \frac{I}{\sigma A}$ A : surface area
 σ : conductivity

H -field (outside): $\vec{H} = \hat{\phi} \frac{I}{2\pi\rho_0}$ ρ_0 : radius of cylinder

NPTEL ONLINE
CERTIFICATION COURSES

So, \vec{E} cross \vec{H} if we put together, this \vec{E} cross \vec{H} and take the cross product of these two quantities, then we can represent that \vec{E} cross \vec{H} equal to minus $\hat{\rho}$ unit vector of ρ that is the radius vector direction by into I^2 by twice π ρ σ into A .

(Refer Slide Time: 22:40)

Cylindrical conductor

From the curved surface

$$\int_{\phi=0}^{2\pi} \int_{z=0}^L (\vec{E} \times \vec{H}) \cdot \hat{n} \rho_0 d\phi dz = \frac{I^2}{(2\pi\rho_0)\sigma A} \rho_0 \left(\int_{\phi=0}^{2\pi} d\phi \right) \int_{z=0}^L dz$$

$$\oint (\vec{E} \times \vec{H}) \cdot \hat{n} da = -I^2 \frac{L}{A\sigma} = -I^2 R \quad R: \text{conductor resistance}$$

NPTEL ONLINE
CERTIFICATION COURSES

So, this is the value of the Poynting vector and from the curved surface; if you consider the Poynting vector, then we can see that we have to take the integration for ϕ which is about the complete azimuth that is from 0 to 2 π and for a certain length L of the conductor which will be from z equal to 0 to L then, we also write the area elementary

area in cylindrical coordinate systems that is equal to $\rho d\phi dz$ and that should be equal to this quantity is the constant; we have to take the integration of ϕ equal to 0 to 2π and L and for z it will be z equal to 0 to L . So, this is a mistake.

So, by doing that $\mathbf{E} \times \mathbf{H} \cdot \mathbf{n} da$ is equal to minus $I^2 R$ by $A\sigma$; that L by $A\sigma$ is equal to the resistance, for resistance we write ρL by A and in terms of conductivity, we write the resistance L by $A\sigma$. So, this quantity represents that minus $I^2 R$. So, this is a known quantity which appears in the textbook that this is the joules loss heating loss.

(Refer Slide Time: 24:14)

Cylindrical conductor

$$\oint (\vec{E} \times \vec{H}) \cdot \hat{n} da = -I^2 R \Rightarrow \text{Dissipated power in the conductor}$$

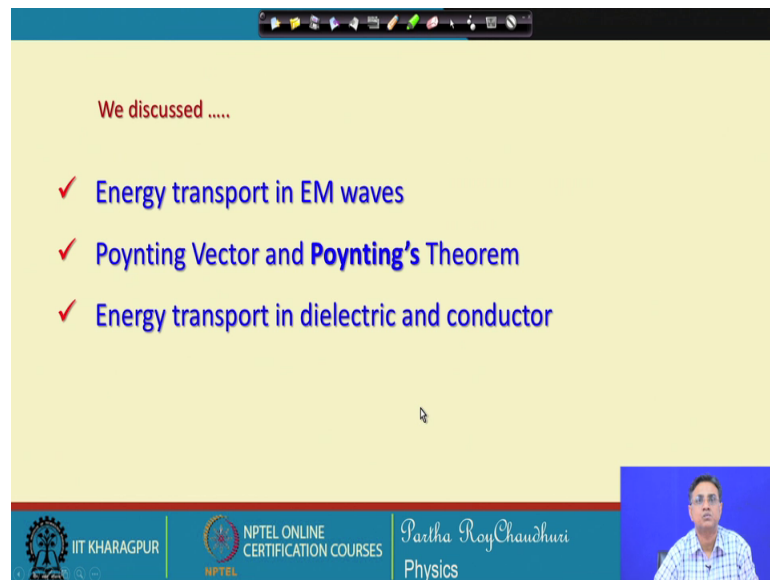

$$\int \vec{J} \cdot \vec{E} dV = \sigma \int E^2 dV$$

$$= \sigma \frac{I^2}{\sigma^2 A^2} AL = I^2 R$$

 NPTEL ONLINE CERTIFICATION COURSES

So, in the case of a cylindrical conductor which carries a current I , we can see that the Poynting vector if you calculate the Poynting vector, but the curved surface; then it really gives you $I^2 R$ with the negative sign, it tells you that this amount of energy is dissipated out and away from the conductor. And $\mathbf{J} \cdot \mathbf{E} dV$ will be equal to $\sigma E^2 dV$. So, this quantity is the loss this quantity is the loss. So, that is equal to σ integration of $E^2 dV$; if I substitute for E^2 , then we again end up with the same value that is $I^2 R$; that means, the energy which is flowing out is equal to the dissipation of through at the conductor which is carrying a current I .

(Refer Slide Time: 25:15)

We discussed

- ✓ Energy transport in EM waves
- ✓ Poynting Vector and **Poynting's Theorem**
- ✓ Energy transport in dielectric and conductor

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Partha RoyChaudhuri
Physics

So, by this discussion we have considered the energy transport in electromagnetic waves which is primarily represented by the Poynting vector and through the Poynting's theorem, that the total amount of electromagnetic energy that is flowing inside a certain volume of space through which the electromagnetic wave is propagating will be equal to the amount of energy that is leaving that space plus the amount of energy which is lost within that volume. So, energy transport in the case of a dielectric medium as well as in the case of a conducting medium we have also calculated.
