

**Introduction to Non-Linear Optics and its Applications**  
**Prof. Samudra Roy**  
**Department of Physics**  
**Indian Institute of Technology, Kharagpur**

**Lecture – 30**  
**1st, 2nd, 3rd order QPM, SHG under depleted pump**

So, welcome student to the next class of introduction to Non-Linear Optics and its Application, this is lecture number 30. So, in the previous class so, we have learned something about the quasi phase matching mainly the calculation part, in quasi phase matching the important thing is that we have an arrangement where the value of  $d$  is periodically changing.

Here the periodical periodically changing this is the value the sign of  $d$  value is changing periodically from plus 1 to minus 1. So, now, we will going to calculate and try to find out that once we have this kind of function in our hand, how this can affect the evolution of the second harmonic. And the phase that is created due to the phase mismatch which is the  $\Delta k$  term  $k_2 - 2k_1$ , how it is compensating that term that we will going to calculate today.

**Topics**

**Nonlinear Optics**

- ✓ Calculation of quasi phase matching (QPM)
- ✓ Realistic calculation of SHG

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Dr. Samudra Roy  
Department of Physics

So, today we have two topics to discuss one is calculation of quasi phase matching and second is realistic calculation of second harmonic generation. So, realistic calculation of

the second harmonic generation is a different part that we will start today, but let us first find out what is the quasi phase matching calculation.

(Refer Slide Time: 01:29)

Quasi Phase matching

$$\frac{dE_2^{(2\omega)}}{dz} = i \frac{d(z)\omega}{cn_2} E_1^2 e^{-i\Delta kz}$$

$$\frac{dE_2^{(2\omega)}}{dz} = i \frac{d_0\omega}{cn_2} E_1^2 \sum_{m=-\infty}^{\infty} G_m e^{i(mK_Q - \Delta k)z}$$

$$\frac{dE_2^{(2\omega)}}{dz} = i \frac{d_0\omega}{cn_2} E_1^2 [G_0 e^{-i\Delta kz} + G_1 e^{i(K_Q - \Delta k)z} + G_{-1} e^{-i(K_Q + \Delta k)z} + \dots]$$

$$\frac{dE_2^{(2\omega)}}{dz} = i \frac{d_0\omega}{cn_2} E_1^2 [G_0 e^{-i\Delta kz} + G_1 e^{i(K_Q - \Delta k)z} + G_{-1} e^{-i(K_Q + \Delta k)z} + \dots]$$

So, if we see that the quasi phase matching for quasi phase matching the  $d$  is now a function of  $z$  that is the important part. The equation of second harmonic whatever the equation is written here in this slide is exactly the same that we have already derived previously. Only important inclusion here is now,  $d$  is a function of  $z$ ; that means, there is a variation over  $G$  if  $d$  is a periodic function.

Then we know that  $d$  can be written in this form, we use this in the previous class.  $dz$  can be represented in this particular form  $G_m e^{i(mK_Q - \Delta k)z}$ . Where  $m$  goes from minus infinity to infinity. Once we write this  $dz$ , then readily we have an expression or the relation over  $d$  which suggests that over a period  $\lambda_d$  has a same value. Since, we have this condition, I can write  $d$  in this particular form we have already proved in the last class.

If we use this value if we use this value here the value of  $d$ , then we can write in total it is  $G_m e^{i(mK_Q - \Delta k)z}$  because of this minus  $ik$  term and  $z$  over some. Now once we have this, I can expand this term as a function of  $m$  by changing the value of  $m$ . So,  $d^2/dz^2 = i \frac{d_0\omega}{cn_2} E_1^2$  this is the constant term and then I expand this term so first term if I put 0 this term will be 0 this term will be 0. So,  $z$

0 e to the power i delta kz that is some sort of term that we already have this is if there is no KQ then we will get some term like this.

Now, this from the second term the contribution of KQ is there, so if I put m equal to 1 we have KQ plus delta kz if I have km equal to minus 1 I should have z of minus 1 e to the power i KQ plus delta kz and so on. If I write what should be the term for m equal to 2 it should be G 2 e to the power i 2 of KQ minus delta kz what should be the term of m equal to 3 it is G 3 e to the power of i 3 KQ minus delta k into z and so on.

For the negative case I just put a negative sign here when I put a negative sign I need to put a negative sign. So, this negative sign and this negative sign I can take common then it should be minus of i 2 KQ plus delta kz when m equal to minus 2 and so on, so this term will go on ok.

(Refer Slide Time: 05:25)

The slide contains the following mathematical content:

$$\frac{dE_2^{(2\omega)}}{dz} = i \frac{d_0 \omega}{c n_2} E_1^2 \left[ G_0 e^{-i \Delta k z} + G_1 e^{i(K_Q - \Delta k)z} + G_{-1} e^{-i(K_Q + \Delta k)z} + \dots \right]$$

↓ (Integrating)

$$E_2^{(2\omega)} = i \frac{d_0 \omega}{c n_2} E_1^2 \left[ G_0 e^{-i \Delta k z / 2} \frac{\sin(\Delta k z / 2)}{(\Delta k / 2)} + G_1 e^{i(K_Q - \Delta k)z / 2} \frac{\sin(K_Q - \Delta k)z / 2}{(K_Q - \Delta k) / 2} + \dots \right]$$

Now at  $K_Q = \Delta k$

$$E_2^{(2\omega)}(z) \approx i \frac{d_0 \omega}{c n_2} E_1^2 G_1 z$$

$$G_1 = \frac{2}{\pi} \sin(\pi D) = \frac{2}{\pi} \quad \left( \text{if } D = \frac{1}{2} \right)$$

$$d_{eff} = d_0 G_1 = d_0 \frac{2}{\pi}$$

$$G_m = \frac{2}{m\pi} \sin(m\pi D)$$

Handwritten notes in blue ink include:  $\frac{dE_2}{dz} = i \frac{d_0 \omega}{c n_2} E_1^2$  and  $K_Q = \Delta k$ .

So, the next slide if I go this is the expansion of d E to dz, now the next step is to find out E 2 that is our goal, but before doing that I need to I need to make some comment here or try to draw your attention that here in G 1 term. We already have here in G 1 term we already have a phase which is KQ minus delta k, this is the phase that already there if I forget about the quasi phase matching term.

If I write only the second harmonic generation term E 2 this differential equation term it was initially i of d of omega divided by n 2 c e to the power E 1 square and the phase

term was  $e$  to the power of minus of  $i \Delta k z$ , this was the term that we have without any kind of periodicity,  $d$  was only a constant term.

So, the first contribution if I see the first contribution of this term is something like this, but here  $d_0$  and  $z_0$  are the 2 terms, which is basically is  $d$  term slightly modified kind of  $d$ . But from the second term onwards what happened that we have a term in phase which is related to  $kq$ ; that means, there is there will be first case what was the phase matching  $\Delta k$  equal to 0 is the phase matching condition.

But for the second case the phase matching condition appear when  $KQ$  is equal to  $\Delta k$ ; that means, phase matching condition is now with  $KQ$  term. So,  $KQ$  is included and then here also we have some sort of phase term, but  $KQ$  equal to minus  $\Delta k$  is our phase matching, in the similar way if I go on with higher values of  $m$ .

(Refer Slide Time: 07:45)

The slide content is as follows:

$$\frac{dE_2^{(2\omega)}}{dz} = i \frac{d_0 \omega}{c n_2} E_1^2 [G_0 e^{-i \Delta k z} + G_1 e^{i(K_Q - \Delta k)z} + G_{-1} e^{-i(K_Q + \Delta k)z} + \dots]$$

↓ (Integrating)  $G_2 e^{i(K_Q - \Delta k)z}$

$$E_2^{(2\omega)} = i \frac{d_0 \omega}{c n_2} E_1^2 \left[ G_0 e^{-i \Delta k z / 2} \frac{\sin(\Delta k z / 2)}{(\Delta k / 2)} + G_1 e^{i(K_Q - \Delta k)z / 2} \frac{\sin(K_Q - \Delta k)z / 2}{(K_Q - \Delta k) / 2} + \dots \right]$$

Now at  $K_Q = \Delta k$

$$E_2^{(2\omega)}(z) \approx i \frac{d_0 \omega}{c n_2} E_1^2 G_1 z$$

$$G_1 = \frac{2}{\pi} \sin(\pi D) = \frac{2}{\pi} \quad \left( \text{if } D = \frac{1}{2} \right)$$

$$d_{eff} = d_0 G_1 = d_0 \frac{2}{\pi}$$

$G_m = \frac{2}{m\pi} \sin(m\pi D)$

Dr. Samudra Roy  
Department of Physi

Then the next higher order term is  $G_2$  we which we have already shown that here the condition of phase matching is this. So,  $2 KQ$  minus  $\Delta k$  equal to 0 is our phase matching this is  $\Delta k$  our phase matching well. So, once we have this expansion the next thing is to integrate it. So, if I integrate we know what should be the value for the first case it is some sort of sin function.

So,  $\sin$  divided by  $\sin \Delta k z$  divided by  $2 \Delta k$  by  $2$  this is a old term that we have already calculated, second term we will have exactly the similar form only  $\Delta k$  will be

replaced by  $K_Q$  minus  $\Delta k$ . So, we will have again have sin of these things and then here we have a mistake it should be  $K_Q$  this  $z$  will be outside. So, here also this will be outside  $K_Q \Delta k$  multiplied by  $z$ , so we will have a sin term also here and so on.

After integration the next thing is what happened we will put our phase matching  $K_Q$  is equal to  $\Delta k$ , that is a phase matching that is a quasi phase matching we call the first order quasi phase matching. So, when we put  $K_Q$  equal to  $\Delta k$  then you can see readily you can find that only the major contribution will come from this term here if I put  $K_Q$  equal to  $\Delta k$ .

(Refer Slide Time: 09:29)

The slide content is as follows:

$$\frac{dE_2^{(2\omega)}}{dz} = i \frac{d_0 \omega}{c n_2} E_1^2 [G_0 e^{-i\Delta k z} + G_1 e^{i(K_Q - \Delta k)z} + G_{-1} e^{-i(K_Q + \Delta k)z} + \dots]$$

↓ (Integrating)

$$E_2^{(2\omega)} = i \frac{d_0 \omega}{c n_2} E_1^2 \left[ G_0 e^{-i\Delta k z/2} \frac{\sin(\Delta k z/2)}{(\Delta k/2)} + G_1 e^{i(K_Q - \Delta k)z/2} \frac{\sin(K_Q - \Delta k)z/2}{(K_Q - \Delta k)/2} + \dots \right]$$

Now at  $K_Q = \Delta k$

$$E_2^{(2\omega)}(z) \approx i \frac{d_0 \omega}{c n_2} E_1^2 G_1 z$$

Handwritten note:  $\frac{\sin K_Q z/2}{\Delta k/2}$

$$G_1 = \frac{2}{\pi} \sin(\pi D) = \frac{2}{\pi} \quad \left( \text{if } D = \frac{1}{2} \right)$$

$$d_{eff} = d_0 G_1 = d_0 \frac{2}{\pi}$$

$$G_m = \frac{2}{m\pi} \sin(m\pi D)$$

NPTEL ONLINE CERTIFICATION COURSES  
Dr. Samudra Roy  
Department of Physi

This term will be  $\sin$  of  $K_Q z$  by 2 divided by  $K_Q$  by 2 it will not going to get any high value because it is some sort of  $\sin$  function or if I write in terms of  $K_Q$  it is a sing function. So, we know that the  $\sin$  function got a maximum when these and these are 0 tends to 0, but here we find that it is not the case; What about the other terms, so higher other terms the higher other terms.

(Refer Slide Time: 10:06)

The slide shows the following mathematical steps:

$$\frac{dE_2^{(2\omega)}}{dz} = i \frac{d_0 \omega}{c n_2} E_1^2 [G_0 e^{-i\Delta k z} + G_1 e^{i(K_Q - \Delta k)z} + G_{-1} e^{-i(K_Q + \Delta k)z} + \dots]$$

↓ (Integrating)

$$E_2^{(2\omega)} = i \frac{d_0 \omega}{c n_2} E_1^2 \left[ G_0 e^{-i\Delta k z/2} \frac{\sin(\Delta k z/2)}{(\Delta k/2)} + G_1 e^{i(K_Q - \Delta k)z/2} \frac{\sin(K_Q - \Delta k)z/2}{(K_Q - \Delta k)/2} + \dots \right]$$

Now at  $K_Q = \Delta k$

Handwritten notes in blue ink:  $\sin K_Q / \sin K_Q \neq K_Q$ ,  $\lim_{K_Q \rightarrow \Delta k} \frac{\sin(K_Q - \Delta k)z/2}{(K_Q - \Delta k)/2} = z$

$$E_2^{(2\omega)}(z) \approx i \frac{d_0 \omega}{c n_2} E_1^2 G_1 z$$

$$G_1 = \frac{2}{\pi} \sin(\pi D) = \frac{2}{\pi} \quad \left( \text{if } D = \frac{1}{2} \right)$$

$$d_{eff} = d_0 G_1 = d_0 \frac{2}{\pi}$$

A boxed equation:  $G_m = \frac{2}{m\pi} \sin(m\pi D)$

Footer: IIT KHARAGPUR, NPTEL ONLINE CERTIFICATION COURSES, Dr. Samudra Roy, Department of Physics

For example if I write G minus 1 and put KQ is equal to delta k we eventually have a term e to the power of minus i 2 of in in in terms of sin after integration we will have a sin term. So, we will have G of 2 sin this term will be 2 KQ and minus k, so minus k will be represented by plus minus KQ minus delta k is represented by minus KQ. So, we will eventually have sin of KQ divided by some term which is again KQ so again we will find that this term will not going to vanish because KQ is equal to delta k it is not 0.

Only contribution we will have this and this term tends to 0 this term tends to 0 and this term tends to 0; that means, this term tends to 1 when we have KQ is equal to delta k. Under that condition I can write E 2 is approximately equal to i d 0 omega c into E 1 square which we have already have multiplied by the coefficient G 1 and the limit at KQ minus delta k tends to 0 this limit this will gives you z so we will have a z here.

Now, G 1 is this because Gm is equal to 2 divided by m pi sin m pi d, so G 1 can be represented in terms of this quantity. So, G 1 is 2 pi if I put m equal to 1 it should be 2 divided by pi sin of pi d because m is 1. And now if I say my duty cycle d is equal to half then it should be 2 divided by pi because d half means sin of pi by 2 it is 1. So, we have the d half so if I now write this G 1 and d 0 together we will have an effective d this effective d is nothing, but d 0 divided by 2 pi.

So, we can see that the first contribution which is containing G 1 term in this case this d effective is less than d 0 by a factor, because d effective is d 0 multiplied by 2 by pi and

$\pi$  is 3 point 1 4 so; that means, we will have a quantity which is less than 1 that is multiplied to  $d$ . So,  $d$  is reduced a bit, but we still have a contribution and this contribution basically give rise to second harmonic. All the other contribution will not going to give any kind of phase matching, so this term will die out very soon. So, only term that will be there is this so if I now try to find out what are the other possibilities of phase matching.

(Refer Slide Time: 13:13)

For 1<sup>st</sup> order QPM:  $G_m = \frac{2}{m\pi} \sin(m\pi D)$   
 $K_Q = \Delta k$

For 2<sup>nd</sup> order QPM:  $2K_Q = \Delta k$

For 3<sup>rd</sup> order QPM:  $3K_Q = \Delta k$

Vector Diagram

$k_1$   $k_1$   $K_Q$   
 $k_2$

$\Delta k = k_2 - 2k_1$

$D = \frac{c}{\lambda} = \frac{1}{4}$

Dr. Samudra Roy  
 Department of Physics

Then  $K_Q$  equal to  $\Delta k$  is not only not only the 1<sup>st</sup> phase matching condition that one can have in this quasi phase matching, but  $2 K_Q$  is equal to  $\Delta k$  that is another one  $3 K_Q$  is equal to  $\Delta k$  is another one. So, on I will find the higher and higher order phase matching, but you have to be remember that if I for example, we can have a system where  $2 K_Q$  equal to  $\Delta k$  is our phase matching condition then which of the term that is responsible is our  $G_2$ .

Now, if I try to find out  $G_2$  with the duty cycle  $d$  is equal to half then  $G_2$  is what was our  $G_m$   $G_m$  was  $2$  divided by  $m \pi$  and then  $\sin$  of  $m \pi$  multiplied by the duty cycle  $d$  that was the form of  $G_m$ . Now suppose we have second order phase matching for second order phase matching the value of  $m$  is  $2$ . Now I try to find out what is my  $G_2$  because  $G_2$  will be effective on gen on generating of second harmonic.

So,  $G_2$  will be  $2$  divided by  $2 \pi$  because  $m$  is  $2$  and then  $\sin$  of  $2 \pi$  multiplied by  $d$  this first term  $2 2$  will cancel out. So, we will have  $1$  by  $\pi \sin$  of  $\pi$  because  $d$  is half, but  $\sin$

of  $\pi$  we know that this is 0 since  $\sin(\pi) = 0$ ; that means, even though we have a second order phase matching condition we can have  $G_2$ , but the contribution of the  $G_2$  is 0.

So, second order phase matching the contribution of  $G_2$  is 0; that means, we will not going to get any kind of second harmonic generation even the phase matching is there be careful about that because the coefficient  $G_2$  will going to vanish. Why it is vanishing that is interesting and it is vanishing because of the  $d$  value we are using this duty cycle equal to half, but the duty cycle  $d$  is represented by 1 divided by big lambda. Now, if I say 1 divided by big lambda this ratio is 1 by 4 because this is in our hand, then you can readily find that  $d$  is 1 by 4 and this value is  $\pi$  by 2 and then again you start getting  $G_2$  because here the  $G_2$  is not equal to 0, but 1 by  $\pi$ .

So, in order to excite the second order quasi phase matching condition the important thing that you need to take care is the duty cycle. If you change the duty cycle there is a possibility that you will get  $G_2$  not equal to if you retain with a previous duty cycle that is half. So, with this periodicity what happened we will not going to get any kind of second order quasi phase matching even though the phase matching is there, but the effective contribution will be 0.

So, next here we will going to conclude our topic ok, so before that we have something to say regarding the vector diagram. In vector diagram this is a collinear kind of phase matching if I write this vector diagrams you can readily see that  $k_2 - \Delta k$  is equal to  $k_1$ , and if I write the first order it is  $k_1 - \Delta k$  is equal to 0.

(Refer Slide Time: 17:12)

For 1<sup>st</sup> order QPM:  $K_Q = \Delta k$

For 2<sup>nd</sup> order QPM:  $2K_Q = \Delta k$

For 3<sup>rd</sup> order QPM:  $3K_Q = \Delta k$

**Vector Diagram**

Diagram showing vectors  $k_1$ ,  $k_1$ , and  $K_Q$  (red arrow) pointing right, and a green arrow  $k_2$  pointing right below them. A blue checkmark is above  $K_Q$ . Handwritten notes below the diagram:  $\Delta k = k_2 - 2k_1$  and  $K_Q - \mathcal{P} = 0$ .

Dr. Samudra Roy  
Department of Physics

So, delta k can be in the vector diagram can be represented with this and this KQ is basically the vector which is associated because of the periodicity that is there because of the periodic d function. So, after that this is the end of the study of quasi phase matching. So, now, we will going to start a new topic which is the realistic calculation of second harmonic generation.

(Refer Slide Time: 17:48)

**Amplitude and phase calculation for SHG**

For phase matching condition ( $\Delta k = 0$ ) we have,

$$\frac{dE_1^{(\omega)}}{dz} = i \frac{d\omega}{cn_1} E_2 E_1^*$$

$$\frac{dE_2^{(2\omega)}}{dz} = i \frac{d\omega}{cn_2} E_1^2$$

$$E_1(z) = u_1(z) e^{i\phi_1(z)}$$

$$E_2(z) = u_2(z) e^{i\phi_2(z)}$$

$$\frac{dE_1^{(\omega)}}{dz} = \left( \frac{\partial u_1}{\partial z} + i u_1 \frac{\partial \phi_1}{\partial z} \right) e^{i\phi_1} = i \frac{d\omega}{cn_1} u_1 u_2 e^{i(\phi_2 - \phi_1)}$$

$$\left( \frac{\partial u_1}{\partial z} + i u_1 \frac{\partial \phi_1}{\partial z} \right) = i \frac{d\omega}{cn_1} u_1 u_2 e^{i\theta(z)}$$

$$\theta(z) = (\phi_2 - 2\phi_1)$$

**Amplitude equation:**

$$\frac{\partial u_1}{\partial z} = - \frac{d\omega}{cn_1} u_1 u_2 \sin \theta$$

**Phase equation:**

$$\frac{\partial \phi_1}{\partial z} = \frac{d\omega}{cn_1} u_2 \cos \theta$$

$$\frac{dE_2^{(2\omega)}}{dz} = \left( \frac{\partial u_2}{\partial z} + i u_2 \frac{\partial \phi_2}{\partial z} \right) e^{i\phi_2} = i \frac{d\omega}{cn_2} u_1^2 e^{2i\phi_1}$$

$$\left( \frac{\partial u_2}{\partial z} + i u_2 \frac{\partial \phi_2}{\partial z} \right) = i \frac{d\omega}{cn_2} u_1^2 e^{-i\theta(z)}$$

**Amplitude equation:**

$$\frac{\partial u_2}{\partial z} = \frac{d\omega}{cn_2} u_1^2 \sin \theta$$

**Phase equation:**

$$\frac{\partial \phi_2}{\partial z} = \frac{d\omega}{cn_2} \frac{u_1^2}{u_2} \cos \theta$$

Dr. Samudra Roy  
Department of Physics

So, this realistic calculation was important, because in the realistic calculation we will not going to consider the electric field having the frequency omega or the fundamental

electric field is constant because it is also changing we have 2 coupled equations. So, if I see these equations so let us go back to the equations. So, under phase matching condition  $\Delta k = 0$  we have 2 equations in our hand to remember.

Both the equations are coupled to each other and in order to find out  $k_2$  initially what we have done we take this  $E_1$  as a constant and then integrate when we integrate we find that  $E_2$  is proportional to  $z$  or the power is proportional to  $z^2$ . So, when we put the efficiency curve it was like this, but we also mention that this is not realistic. So, over  $z$   $\eta$  of  $z$  was something like this, but we also mention that this is not the correct representation of the correct representation of this efficiency. So, we need to find out the realistic calculations.

So, now, we will go to do that, in order to do that what we do is we divide the total electric field  $E_1$  into 2 parts 1 is amplitude part  $u_1 z$  and in phase part  $u_1 E$  to the power  $i \phi_1$   $i \phi_1 z$ . So, both are now varying with  $z$  for  $E_2$  also we will divide into amplitude and phase in this way. Once we have the amplitude and phase separately where  $u_1$  and  $u_2$  are the real quantity also  $\phi_1$  and  $\phi_2$  has a real quantity this complex amplitude we can also divide into  $E$  to the power  $i r$   $E$  to the power  $i \theta$  forms.

So, here it is something like this so now, we will have a derivative over  $E_1$ . So, when we make a derivative over  $E_1$ . So, since  $E_1$  is represented by  $E_1 E$  to the power  $i \phi_1$  so that derivative of  $E_1$  and  $\phi_1$  can give this form  $du_1/dz + i u_1 d\phi_1/dz$  through our  $i \phi_1$ . And this quantity is in from the right hand side I write it is  $i d\omega/cn_1$  and  $E_2 E_1$  can also represent in terms of  $E_1$  and  $E_2 u_1$  and  $u_2$  multiplied  $E$  to the power  $i \phi_2$  minus  $\phi_1$  because there is a start. So, that is why minus  $\phi_1$  is here, so this phase is associated with that.

So, in the left hand side we have  $du_1/dz + i u_1 d\phi_1/dz$   $i d\omega/cn_1$   $u_1$  into  $E$  to the power  $i \theta$   $z$ . Where  $\theta$  is  $\phi_2$  minus  $2 \phi_1$  this is the phase difference between these two, but not the total phase difference this is some quantity  $\phi_2$  minus  $2 \phi_1$  the phase difference should be  $\phi_2$  minus  $\phi_1$ , but  $2$  term is here. Now, the amplitude equation we had an equation here you should look carefully this is our equation. So, this equation is a complex equation in the left hand side the real and complex.

(Refer Slide Time: 21:19)

**Amplitude and phase calculation for SHG**

For phase matching condition ( $\Delta k = 0$ ) we have,

$$\frac{dE_1^{(\omega)}}{dz} = i \frac{d\omega}{cn_1} E_2 E_1^*$$

$$\frac{dE_2^{(2\omega)}}{dz} = i \frac{d\omega}{cn_2} E_1^2$$

$$E_1(z) = u_1(z) e^{i\phi_1(z)}$$

$$E_2(z) = u_2(z) e^{i\phi_2(z)}$$

$$\frac{dE_1^{(\omega)}}{dz} = \left( \frac{\partial u_1}{\partial z} + i u_1 \frac{\partial \phi_1}{\partial z} \right) e^{i\phi_1} = i \frac{d\omega}{cn_1} u_1 u_2 e^{i(\phi_2 - \phi_1)}$$

$$\left( \frac{\partial u_1}{\partial z} + i u_1 \frac{\partial \phi_1}{\partial z} \right) = i \frac{d\omega}{cn_1} u_1 u_2 e^{i\theta(z)}$$

$$\theta(z) = (\phi_2 - 2\phi_1)$$

Amplitude equation:

$$\frac{\partial u_1}{\partial z} = - \frac{d\omega}{cn_1} u_1 u_2 \sin \theta$$

Phase equation:

$$\frac{\partial \phi_1}{\partial z} = \frac{d\omega}{cn_1} u_2 \cos \theta$$

$$\frac{dE_2^{(2\omega)}}{dz} = \left( \frac{\partial u_2}{\partial z} + i u_2 \frac{\partial \phi_2}{\partial z} \right) e^{i\phi_2} = i \frac{d\omega}{cn_2} u_1^2 e^{2i\phi_1}$$

$$\left( \frac{\partial u_2}{\partial z} + i u_2 \frac{\partial \phi_2}{\partial z} \right) = i \frac{d\omega}{cn_2} u_1^2 e^{-i\theta(z)}$$

Amplitude equation:

$$\frac{\partial u_2}{\partial z} = \frac{d\omega}{cn_2} u_1^2 \sin \theta$$

Phase equation:

$$\frac{\partial \phi_2}{\partial z} = \frac{d\omega}{cn_2} u_1^2 \cos \theta$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Dr. Samudra Roy, Department of Physics

So, we know that if  $x + iy = a + ib$  then we can write  $x$  is equal to  $a$  and  $y$  is equal to  $b$ . We will going to use the same thing the real part of the left hand side will equal to real part, and if we do we will find this equation that  $du_1/dz$  is equal to  $u_1 u_2 \sin \theta$  multiplied by  $d\omega/cn_1$  and the imaginary part which is again equal and the eq phase equation  $i$  will get this quantity.

In the similar way we can find the same thing for  $E_2$  and I will not going to explain the entire process because it is already there. So, I ask the student to do this things by yourself to find out these 2 equation for  $E_2$  and you will find that we will get this 2 all the calculations already there, but I am still ask you to do that by yourself this is a very straight forward calculation So, real an imaginary part you can extract out from this 2 so after doing all these calculation when we extract the amplitude and phase equation together.

(Refer Slide Time: 22:29)

Let  $n_1 \approx n_2$ , then

$$\kappa = \frac{d\omega}{cn_1} = \frac{d\omega}{cn_2}$$

Amplitude and phase equation together:

$$\frac{\partial u_1}{\partial z} = -\kappa u_1 u_2 \sin \theta$$

$$\frac{\partial u_2}{\partial z} = \kappa u_1^2 \sin \theta$$

$$u_1 \frac{\partial \phi_1}{\partial z} = \kappa u_1 u_2 \cos \theta$$

$$u_2 \frac{\partial \phi_2}{\partial z} = \kappa u_1^2 \cos \theta$$

$$\frac{d\theta}{dz} = \frac{d\phi_2}{dz} - 2 \frac{d\phi_1}{dz}$$

$$\frac{d\theta}{dz} = \kappa \frac{u_1^2}{u_2} \cos \theta - 2\kappa u_2 \cos \theta$$

$$\frac{d\theta}{dz} = \kappa \cos \theta \left[ \frac{u_1^2}{u_2} - 2u_2 \right]$$

$$\frac{d\theta}{dz} = \frac{\kappa}{u_2} \cos \theta [u_1^2 - 2u_2^2]$$

$$\frac{d}{dz} (\ln u_1^2 u_2) = \frac{1}{u_1^2 u_2} \left( u_1^2 \frac{du_2}{dz} + 2u_1 u_2 \frac{du_1}{dz} \right)$$

$$\frac{d}{dz} (\ln u_1^2 u_2) = \frac{1}{u_1^2 u_2} [u_1^4 \kappa \sin \theta - 2\kappa u_1^2 u_2^2 \sin \theta]$$

$$\frac{d}{dz} (\ln u_1^2 u_2) = \frac{\kappa \sin \theta}{u_2} [u_1^2 - 2u_2^2]$$

$$\frac{d}{dz} (\ln u_1^2 u_2) = \frac{\sin \theta}{\cos \theta} \frac{d\theta}{dz} = -\frac{d}{dz} \ln \cos \theta$$

$$\frac{d}{dz} (\ln u_1^2 u_2 \cos \theta) = 0$$

$$u_1^2 u_2 \cos \theta = \text{const}$$

IIT KHARAGPUR NPTEL ONLINE CERTIFICATION COURSES Dr. Samudra Roy Department of Physics

Then the next thing we can do is to use this thing, now if we use that this  $d\omega/cn_1$  and  $d\omega/cn_2$  are very close if  $n_1$  and  $n_2$  are very close to each other we can write  $d\omega/cn_1$  and  $d\omega/cn_2$  very close to each other and we write it as general coefficient  $\kappa$ . So, when I do that then we will find these things will reduce the calculation significantly.

Now, 2 amplitude equations I can write  $du_1/dz$  is equal to  $-\kappa u_1 u_2 \sin \theta$  and  $du_2/dz$  is  $\kappa u_1^2 \sin \theta$ . This was the 2 amplitude equations. Mind it, the term  $\kappa$  is used in two different cases because  $d\omega/cn_1$  we assume  $n_1$  is very close to  $n_2$ . So, we assume that they might be the same for amplitude case also. We have amplitude equations and this amplitude equation is  $u_1 d\phi_1/dz$  is equal to  $\kappa u_1 u_2 \cos \theta$  and  $u_2 d\phi_2/dz$  is equal to  $\kappa u_1^2 \cos \theta$ .

Now, we know  $\theta$  is equal to  $\phi_2 - 2\phi_1$  so when we make a derivative of  $\theta$ , we will have an additional term  $d\phi_2/dz - 2d\phi_1/dz$ .  $\phi_1 \phi_2$  we can have from here. When I use this  $\phi_1 \phi_2$  we will have an expression of  $d\theta$  which is  $u_1^2 u_2 \cos \theta - 2\kappa u_2 \cos \theta$ , why we were doing all this calculation we will find in the right hand side basically because in the right hand side eventually we get 1 quantity which is conserved over the distance; that means, it is not going to change.

To figure out we need to use this methodology this calculation and in the Boyd book this calculation is there if somebody is interested or see you can go to this book, but all

the calculation is here in this slide. If you do this calculation by your own then you will find that it is not a very critical calculation rather it is a lengthy, but it is not a very critical it is a straight forward calculation.

Next we will find one very important quantity and that is  $\log u_1^2 u_2$  when we try to find out  $\log u_1^2 u_2$ , if you if I make a derivative of  $z = \frac{u_1}{u_2}$  is be there because I am making derivative. So,  $u_1^2$  then the derivative of this quantity which is  $u_1^2$  this plus the derivative of  $2 u_1 u_2$ . So, we will have this again we will going to use this  $du_1 dz$  and  $du_2 dz$  from this equation these two equation and we will find one expression like this.

If I simplify this equation we will eventually have one expression  $d dz$  is equal to  $\log$  of  $u_1^2 u_2$   $\kappa \sin \theta$  divided by  $u_2$  and  $u_1^2$  minus  $2 u_1 u_2$ . Now in the right hand side this quantity, we already get here in terms of  $\theta$  if I slightly manipulate this thing this  $\cos \theta$  and all this things I can write  $d \cos \theta$  by  $z$  divided by if I put this  $\cos \theta$  here.

(Refer Slide Time: 26:24)

Let  $n_1 \approx n_2$ , then

$$\kappa = \frac{d\omega}{cn_1} = \frac{d\omega}{cn_2}$$

Amplitude and phase equation together:

$$\frac{\partial u_1}{\partial z} = -\kappa u_1 u_2 \sin \theta$$

$$\frac{\partial u_2}{\partial z} = \kappa u_1^2 \sin \theta$$

$$u_1 \frac{\partial \phi_1}{\partial z} = \kappa u_1 u_2 \cos \theta$$

$$u_2 \frac{\partial \phi_2}{\partial z} = \kappa u_1^2 \cos \theta$$

$$\frac{d\theta}{dz} = \frac{d\phi_2}{dz} - 2 \frac{d\phi_1}{dz}$$

$$\frac{d\theta}{dz} = \kappa \frac{u_1^2}{u_2} \cos \theta - 2\kappa u_2 \cos \theta$$

$$\frac{d\theta}{dz} = \kappa \cos \theta \left[ \frac{u_1^2}{u_2} - 2u_2 \right]$$

Handwritten derivations on the right side of the slide:

$$\frac{d\theta}{dz} = \frac{\kappa \cos \theta (u_1^2 - 2u_2^2)}{u_2}$$

$$\frac{d}{dz} (\ln u_1^2 u_2) = \frac{1}{u_1^2 u_2} \left( u_1^2 \frac{du_2}{dz} + 2u_1 u_2 \frac{du_1}{dz} \right)$$

$$\frac{d}{dz} (\ln u_1^2 u_2) = \frac{1}{u_1^2 u_2} [u_1^4 \kappa \sin \theta - 2\kappa u_1^2 u_2^2 \sin \theta]$$

$$\frac{d}{dz} (\ln u_1^2 u_2) = \frac{\kappa \sin \theta}{u_2} (u_1^2 - 2u_2^2)$$

$$\frac{d}{dz} (\ln u_1^2 u_2) = \frac{\sin \theta}{\cos \theta} \frac{d\theta}{dz} = -\frac{d}{dz} \ln \cos \theta$$

$$\frac{d}{dz} (\ln u_1^2 u_2 \cos \theta) = 0 \quad \theta = \phi_2 - 2\phi_1$$

$$u_1^2 u_2 \cos \theta = \text{const}$$

Dr. Samudra Roy  
Department of Physi...

So,  $1/\cos \theta$  will be this term and now  $\sin \theta$  it is multiplied  $\sin \theta$  by  $\cos \theta$   $d dz$  is equal to  $\log$  of  $d dz$  of  $\ln$  of  $u_1^2 u_2$  this 2 quantity this quantity can again be represented as  $\log$ . So, minus of  $d z \ln \cos \theta$  should be equal to this quantity you look carefully you can really understand what is going on. Now if I combine these two the important very important expression that will come is  $d dz$  of  $\ln u_1^2 u_2$

cos theta is equal to 0; that means,  $u_1^2 u_2 \cos \theta$  is equal to constant this is a very, very important expression that we end up that  $u_1$ ,  $u_2$  and  $\cos \theta$  both are varying independently.

Because,  $u_1$  is a amplitude of the fundamental wave  $u_2$  is amplitude of the second harmonic and  $\theta$  is a difference between their angles different between their phases, but the phase directly it is not different. So,  $\theta$  is  $\phi_2$  minus  $2\phi_1$ ,  $\phi_1$  and  $\phi_2$  are their phases. So,  $\theta$  is difference of this 2 quantity, but they are also changing with respect to  $z$ ; that means,  $\theta$  should be a function of  $z$ .

(Refer Slide Time: 28:00)

$u_1^2 u_2 \cos \theta = \text{cont}$

$E_2(z=0) = 0 \rightarrow u_2(0) = 0$

$u_1^2(z) u_2(z) \cos \theta(z) = \text{cont} = u_1^2(0) u_2(0) \cos \theta(0) = 0$

Hence for all values of  $z$ ,

$u_1^2(z) u_2(z) \cos \theta(z) = 0$

$\theta(z) = \phi_2(z) - 2\phi_1(z) = \pm \pi/2$

Dr. Samudra Roy  
Department of Physi

So,  $u_1 u_2$  so if I now write  $u_1 u_2 \cos \theta$  is equal to constant. So, this means  $u_1$  which is a function of  $z$ ,  $u_2$  which is a function of  $z$ ,  $\cos \theta$  is a function of  $z$  is constant. Now, if I put some boundary condition if I put some boundary condition  $E_2$  at  $z$  equal to 0 is 0 because at the beginning there was no second harmonic so; that means,  $u_2$  at  $z$  equal to 0 has to be 0. When  $u_2$  at  $z$  equal to 0 is 0; that means,  $u_1 z u_2 z \cos \theta$  equal to 0 constant which is same as all the term at 0 point.

So,  $u_1(0) u_2(0) \cos \theta(0)$  that should be equal to the this quantity, because it is a constant throughout the motion. But now we find that this quantity this quantity is 0; that means, whatever the constant we are try to say is 0; that means,  $u_1^2 u_2 u_1^2 z u_2 z$  and  $\cos \theta z$  is 0. Now, again we find a very interesting outcome from this  $u_1$  and  $u_2$   $u_2$  is 0 at  $z$  equal to 0 that is true, but after that  $u_2$  is not equal to 0  $u_1$  is also not

equal to 0 this is multiplied by  $\cos \theta$  and this entire quantity is 0; it is only possible if it is only possible when  $\theta$  has some relation. So,  $\theta = z(\phi_2 - 2\phi_1)$  if this quantity is  $\pm \pi/2$  then only we can say that this is a valid equation.

So, we will find a valid equation here and this valid equation suggests that when they have a phase relationship so; that means, when the second harmonic is generated there is a phase relationship between the second harmonic and the fundamental wave. And this phase relationship is  $\phi_2 - 2\phi_1 = \pm \pi/2$ .

So, we will in the next class we will go to use this phase relationship to find out the parametric generation and all these issues will come. But an important thing is this calculation is lengthy, but an important thing is 1 quantity that is conserved during the propagation is  $u_1^2 u_2 \cos \theta$ . And this  $\cos \theta$  is something where  $\theta$  is represented by the phase of the fundamental and second harmonic wave; this phase relationship  $\phi_2 - 2\phi_1$  and  $\phi_2 - 2\phi_1 \pm \pi/2$  these phase relationships are maintained throughout the distance. So,  $\phi_2 - 2\phi_1$  is always  $\pm \pi/2$  depending on the situation and then it is conserved throughout the propagation.

So, we find a very important outcome today that 1 equation that is not changing and using that we will find out what should be the amplitude and phase evolution over the distance. And we will find in that case that it is not a  $z^2$  dependency, but we have a realistic calculation. So, with this note let me conclude today's class. So, in the next class we will start from here and try to find out more about the second harmonic generation. And how the second harmonic field will go to evolve under realistic conditions that we will go to find using today's outcome. So, with that note let me conclude here see you in the next class.

Thank you for your attention.
