Lecture – 33
Manley – Rowe Relation (3 wave mixing), Parametric down conversion

So, welcome student to the next class of Introduction to Non-Linear Optics and its Application. So, today we will have lecture number 33. So, today in the lecture we have two very important topic.

(Refer Slide Time: 00:33)

Topics

Nonlinear Optics

- ✓ Manley-Rowe Relation (3 wave mixing)
- ✓ Parametric down conversion

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Dr. Samudra Roy
Department of Physics

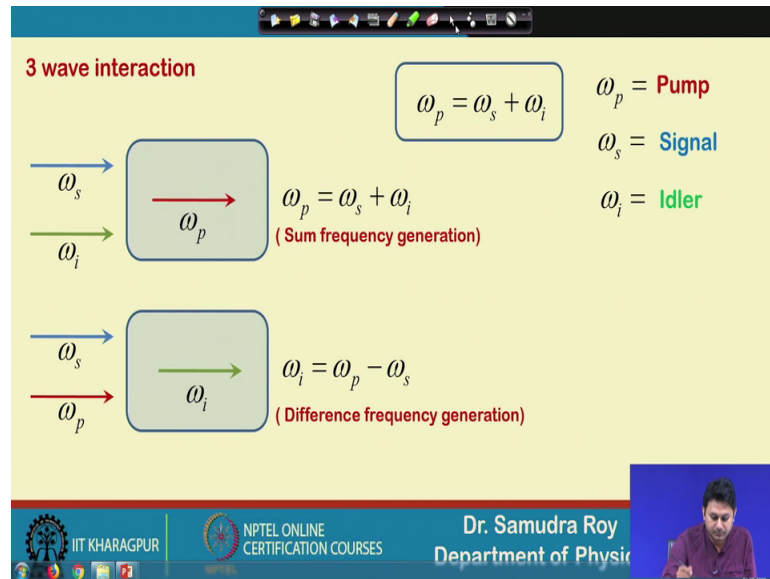

One is the Manley-Rowe relation for 3 wave mixing. This relation we have already discussed for the second harmonic generation when we are discussing about the second harmonic generation process, we have already discuss in detail. So, again this equation will come into the picture when we deal with this 3 wave mixing. This is the general form of the second harmonic generation then a we start a concept call Parametric down conversion.

So, what is parametric down conversion we will try to find? So, the name suggest that we will try to down conversion the there is some sort of down conversion in frequency. So, in second harmonic generation we are launching a frequency ω and getting a frequency 2ω . But for parametric down conversion what happened that we like to

launch a frequency of 2 omega and try to find out whether we are getting to getting a frequency sub harmonic like omega naught.

So, how this process one can initiate and what is the condition to generate this kind of sub harmonic generation we will try to find out. So, let us go back to our slides.

(Refer Slide Time: 01:48)

So, in 3 wave interaction. So, we introduced some kind of nomenclature. So, this nomenclature are very important that we called the omega p as pump the frequency of the pump, omega s as the frequency of the signal and omega i is a idler. So omega p, omega s and omega i they are related to a very simple equation omega p is equal to omega s plus omega i.

So, when I try to find out the sum frequency then we can say omega s plus omega i is equal to omega p. So, omega p is basically the sum frequency and the different frequency we can generate through omega p and omega s and omega p minus; omega s is our different frequency. And omega i is represented by omega p and omega s is given the corresponding different frequency.

In all the cases what happened that we should launch the signal both the cases. So, omega s is the signal that we will launch both the cases. For some frequency with omega s we launch omega i, for different frequency for omega s we launch omega p that is the difference well.

(Refer Slide Time: 03:19)

3 wave interaction

Expressions of the fields

$$E^{(\omega_p)} = \frac{1}{2} [E_p e^{i(k_p z - \omega_p t)} + c.c.]$$

$$E^{(\omega_s)} = \frac{1}{2} [E_s e^{i(k_s z - \omega_s t)} + c.c.]$$

$$E^{(\omega_i)} = \frac{1}{2} [E_i e^{i(k_i z - \omega_i t)} + c.c.]$$

Handwritten note: $\omega_p = \omega_s + \omega_i$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Dr. Samudra Roy, Department of Physics

So, in the next slide we will have the expression of the electric field that we defined in our last class. So, this expression is straight forward that we have an amplitude of pump, signal and idler as E_p , E_s and E_i . The phase is associated with all the expression and inside the phase we have a propagation constant k_p , k_s and k_i for three cases and also the frequency ω_p , ω_s and ω_i . So, 2 frequency 3 frequencies are there ω_p , ω_s and ω_i and they are related to ω_p is equal to ω_s plus ω_i as usual.

So, this equation always valid, we need to consider that ω_p is equal to ω_s plus ω_i this equation is always valid. So, this is our fundamental some sort of fundamental equation. So, based on this equation whatever the treatment we will do that all this treatment.

(Refer Slide Time: 04:28)

Manley-Rowe Relation

$$P_p(z) = I_p(z)A = \frac{1}{2}\epsilon_0 c n_p |E_p(z)|^2 A$$

$$\frac{dP_p(z)}{dz} = \frac{1}{2}\epsilon_0 c n_p A \left[E_p^* \frac{dE_p}{dz} + E_p \frac{dE_p^*}{dz} \right]$$

$$\frac{dP_p(z)}{dz} = \frac{1}{2}\epsilon_0 c n_p A [E_p^* i \kappa_p E_s E_i e^{-i\Delta k z} - E_p i \kappa_p E_s^* E_i^* e^{i\Delta k z}]$$

$$\frac{dP_p(z)}{dz} = \frac{iA}{2}\epsilon_0 c n_p \kappa_p [E_p^* E_s E_i e^{-i\Delta k z} - E_p E_s^* E_i^* e^{i\Delta k z}]$$

$$\frac{dP_p(z)}{dz} = i \frac{A}{2}\epsilon_0 d \omega_p [E_p^* E_s E_i e^{-i\Delta k z} - E_p E_s^* E_i^* e^{i\Delta k z}]$$

$$E^{(\omega_p)} = \frac{1}{2} [E_p e^{i(k_p z - \omega_p t)} + c.c.]$$

$$E^{(\omega_s)} = \frac{1}{2} [E_s e^{i(k_s z - \omega_s t)} + c.c.]$$

$$E^{(\omega_i)} = \frac{1}{2} [E_i e^{i(k_i z - \omega_i t)} + c.c.]$$

$E_p^* E_p = |E_p|^2$

So, today we will try to find out the Manley-Rowe equation. So, the Manley-Rowe equation is something which gives us the conservation of energy or the conservation of 4 numbers.

So, here if I if we see we will find one important thing, pump is represented by I_p multiplied by A , A is a area. So, we know that the intensity is half of $\epsilon_0 c n_p$ and mode of E_p square for pump multiplied by A . If I make a derivative with respect to z of this pump then we will have this term half $\epsilon_0 c n_p A$ which is constant.

And then the derivative of this quantity which is not squares, so two term will appear because $E_p^* E_p$ is our mode of E_p square. So, when you make a derivative there are two functions so, that is why we will first case we have E_p then d/dz of E_p then $E_p d/dz$ of E_p^* . So, once we have these two terms then the next thing is that we will going to replace this quantity, we will going to replace this quantity. Already in the previous class here all the $E_p E_s E_w$ term is there, but in the previous class we have already find out dE_p/dz was $i d\omega_p n_p c E_s E_i e^{-i\Delta k z}$. This was the term; this was the expression that we had derived in our previous class.

(Refer Slide Time: 06:30)

Manley-Rowe Relation

$$P_p(z) = I_p(z)A = \frac{1}{2}\epsilon_0 c n_p |E_p(z)|^2 A$$

$$\frac{dP_p(z)}{dz} = \frac{1}{2}\epsilon_0 c n_p A \left[E_p^* \frac{dE_p}{dz} + E_p \frac{dE_p^*}{dz} \right]$$

$$\frac{dP_p(z)}{dz} = \frac{1}{2}\epsilon_0 c n_p A [E_p^* i \kappa_p E_s E_i e^{-i\Delta k z} - E_p i \kappa_p E_s^* E_i^* e^{i\Delta k z}]$$

$$\frac{dP_p(z)}{dz} = \frac{iA}{2}\epsilon_0 c n_p \kappa_p [E_p^* E_s E_i e^{-i\Delta k z} - E_p E_s^* E_i^* e^{i\Delta k z}]$$

$$\frac{dP_p(z)}{dz} = i \frac{A}{2}\epsilon_0 d\omega_p [E_p^* E_s E_i e^{-i\Delta k z} - E_p E_s^* E_i^* e^{i\Delta k z}]$$

$$E^{(\omega_p)} = \frac{1}{2} [E_p e^{i(k_p z - \omega_p t)} + c.c.]$$

$$E^{(\omega_s)} = \frac{1}{2} [E_s e^{i(k_s z - \omega_s t)} + c.c.]$$

$$E^{(\omega_i)} = \frac{1}{2} [E_i e^{i(k_i z - \omega_i t)} + c.c.]$$

$\frac{dE_p}{dz} = i \frac{d\omega_p}{n_p c} E_s E_i e^{i\Delta k z}$
 $\kappa_p = \frac{d\omega_p}{n_p c}$

Dr. Samudra Roy
 Department of Physics

So, now what we will introduce one term called kappa p which is d omega p divided by n p into c then this expression can be simplified.

(Refer Slide Time: 07:27)

Manley-Rowe Relation

$$P_p(z) = I_p(z)A = \frac{1}{2}\epsilon_0 c n_p |E_p(z)|^2 A$$

$$\frac{dP_p(z)}{dz} = \frac{1}{2}\epsilon_0 c n_p A \left[E_p^* \frac{dE_p}{dz} + E_p \frac{dE_p^*}{dz} \right]$$

$$\frac{dP_p(z)}{dz} = \frac{1}{2}\epsilon_0 c n_p A [E_p^* i \kappa_p E_s E_i e^{-i\Delta k z} - E_p i \kappa_p E_s^* E_i^* e^{i\Delta k z}]$$

$$\frac{dP_p(z)}{dz} = \frac{iA}{2}\epsilon_0 c n_p \kappa_p [E_p^* E_s E_i e^{-i\Delta k z} - E_p E_s^* E_i^* e^{i\Delta k z}]$$

$$\frac{dP_p(z)}{dz} = i \frac{A}{2}\epsilon_0 d\omega_p [E_p^* E_s E_i e^{-i\Delta k z} - E_p E_s^* E_i^* e^{i\Delta k z}]$$

$$E^{(\omega_p)} = \frac{1}{2} [E_p e^{i(k_p z - \omega_p t)} + c.c.]$$

$$E^{(\omega_s)} = \frac{1}{2} [E_s e^{i(k_s z - \omega_s t)} + c.c.]$$

$$E^{(\omega_i)} = \frac{1}{2} [E_i e^{i(k_i z - \omega_i t)} + c.c.]$$

$\frac{dE_p}{dz} = i \kappa_p E_s E_i e^{i\Delta k z}$
 $\kappa_p = \frac{d\omega_p}{n_p c}$

Dr. Samudra Roy
 Department of Physics

And this expression is now d of E p dz is equal to i of kappa p E of s E of i e to the power of i delta k z, I just replace this thing here. So, E p star multiplied by this quantity i kappa kappa p E s E i and e to the power of i minus of delta k ok, in this case there was a minus sign if you remember the previous class. Also, I replace this which is nothing,

but the star of this things when I make a star so, one negative sign will have and this term will plus.

So, we will have a negative sign and plus here and also E s will become E s star and E i become non-star because E i so, here we have star. So, this then E both the cases there was no star. So, it will be E s star E i star ok, this is right. Now, what we will do we will just take kappa p common then i A by 2 epsilon 0 cn p kappa p.

And inside this bracket we have E p star E s E i multiplied by e to the power of minus i delta kz and E p star E s E i star e to the power i delta kz; further I can simplify. So, this epsilon 0 cn p kappa p can be simplified to as epsilon 0 d omega p. Why? Because epsilon 0 cn p multiplied by kappa p and what was my kappa p, kappa p was simply d of omega p so, divided by n p of c. So, this n p c n p c will cancel out we will have d of omega p so, which is here.

(Refer Slide Time: 09:51)

The slide displays the following equations and notes:

$$\frac{dP_p(z)}{dz} = i \frac{A}{2} \epsilon_0 d \omega_p [E_p^* E_s E_i e^{-i\Delta kz} - E_p E_s^* E_i^* e^{i\Delta kz}]$$

Similarly,

$$\frac{dP_s(z)}{dz} = i \frac{A}{2} \epsilon_0 d \omega_s [E_p E_s^* E_i^* e^{i\Delta kz} - E_p^* E_s E_i e^{-i\Delta kz}]$$

$$\frac{dP_i(z)}{dz} = i \frac{A}{2} \epsilon_0 d \omega_i [E_p E_s^* E_i^* e^{i\Delta kz} - E_p^* E_s E_i e^{-i\Delta kz}]$$

Handwritten notes in red ink on the left side of the slide include:

- $\frac{dE_s}{dz} = i \kappa_s E_p E_i$
- $\frac{dE_i}{dz} = i \kappa_i E_p E_s$

A boxed equation at the bottom of the slide states:

$$-\frac{1}{\omega_p} \frac{dP_p}{dz} = \frac{1}{\omega_s} \frac{dP_s}{dz} = \frac{1}{\omega_i} \frac{dP_i}{dz}$$

The slide footer includes the IIT Kharagpur logo, NPTEL ONLINE CERTIFICATION COURSES, and the name of Dr. Samudra Roy, Department of Physics.

Next we will have this form. So, now, in the exactly in the similar way just using other 2 equation, just using other 2 equation d E s dz is equal to i kappa s E p E i star e to the power of i delta k z; this was the expression of E s d E s dz. And in the similar way we have another equation that is this i kappa p kappa i E p E s star e to the power i delta k z. Using these 2 equation again we can find out what is the value of the term dP s d z and dP i dz.

And if you calculate I again I ask the student to do this calculation by yourself and you will get a result something like this and this. And if you compare these three result you will find that whatever you are getting here exactly a similar term you will get here and here; in case of signal and idler. Only difference between these and this is one negative sign and if you have a negative sign here and here, because it is $E_p E_s E_i$ it is $E_p E_p^* E_s E_i$ star $E_s E_i$, but here you have a $E_p E_s^* E_i^*$ which is this term and this term is here.

So, one negative sign is related to this and once you have a negative sign for all these cases then these 3 equation can be represented in terms of a more general equation if I divide this 1 by ω_p here than the right-hand side will be 1 by A^2 and $\epsilon_0 z$ and this in the bracket.

(Refer Slide Time: 12:11)

$$\frac{1}{\omega_p} \frac{dP_p(z)}{dz} = i \frac{A}{2} \epsilon_0 d \omega_p [E_p^* E_s E_i e^{-i \Delta k z} - E_p E_s^* E_i^* e^{i \Delta k z}]$$
 Similarly,

$$\frac{1}{\omega_s} \frac{dP_s(z)}{dz} = i \frac{A}{2} \epsilon_0 d \omega_s [E_p E_s^* E_i^* e^{i \Delta k z} - E_p^* E_s E_i e^{-i \Delta k z}]$$

$$\frac{1}{\omega_i} \frac{dP_i(z)}{dz} = i \frac{A}{2} \epsilon_0 d \omega_i [E_p E_s^* E_i^* e^{i \Delta k z} - E_p^* E_s E_i e^{-i \Delta k z}]$$

$$\frac{1}{\omega_p} \frac{dP_p}{dz} = \frac{1}{\omega_s} \frac{dP_s}{dz} = \frac{1}{\omega_i} \frac{dP_i}{dz}$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Dr. Samudra Roy, Department of Physics

The similar way if I write 1 by ω_s here so, this ω_s will not be there and we have these something in bracket. So, these and this term 1 by ω_p , this term and this term are negative to each other. So, this is equal to minus of this, in the similar way this is this term are same. So, I can write one expression that 1 by ω_p with the negative term dP/dz is equal to 1 by ω_s dP/dz is equal to 1 by ω_i dP/dz . So, this equation which is in the bracket or which is in inside this box is called the Manley-Rowe relation.

This is the same equation that we have derived in case of second harmonic generation. We are eventually getting the similar kind of equation, but since we are dealing with 3

waves this equation looks slightly different. And instead of having 12 equation 2 relation we have 3 expression because of the signal idler and pump. Now, if the signal or idler are same then we have a two term here and these two term basically suggest that we are generating second harmonic.

But here since, we are not considering explicitly the second harmonic is generated because second harmonic is a special case. So, if any frequency ω_s and ω_i are generated from a pump ω_p and then I can write this Manley-Rowe equation. And this Manley-Rowe equation suggest that they should follow this identity.

(Refer Slide Time: 14:01)

$$\frac{1}{\omega_p} \frac{dP_p}{dz} = \frac{1}{\omega_s} \frac{dP_s}{dz} = \frac{1}{\omega_i} \frac{dP_i}{dz} = \Gamma \quad (\text{a constant})$$

$$\frac{dP_p}{dz} + \frac{dP_s}{dz} + \frac{dP_i}{dz} = \Gamma(\omega_i + \omega_s - \omega_p) = 0$$

$$P = P_p + P_s + P_i$$

$$\frac{dP}{dz} = \Gamma \times 0 = 0 \quad (\omega_p = \omega_s + \omega_i)$$

So total power (P) is conserved.

From this Manley-Rowe equation we can further derive important outcomes. And one important outcome is this is our Manley-Rowe equation that $\frac{1}{\omega_p} \frac{dP_p}{dz} = \frac{1}{\omega_s} \frac{dP_s}{dz} = \frac{1}{\omega_i} \frac{dP_i}{dz}$. If this is a constant Γ then I can write $\frac{dP_p}{dz} = \Gamma \omega_p$. So, I can write this right $\frac{dP_p}{dz}$ is equal to minus of $\omega_p \Gamma$ and $\frac{dP_s}{dz}$ I can write $\omega_s \Gamma$ and $\frac{dP_i}{dz}$ I can write $\omega_i \Gamma$.

Now, if I add these three things together like we have done here so, Γ will be common and we can write $\omega_i + \omega_s - \omega_p$ this. Now, we know that ω_p is equal to $\omega_s + \omega_i$ that is true in all cases. So, from this equation I can write that this term is 0. So, total power if I write $P_p + P_s + P_i$ so, $\frac{dP}{dz} = 0$, but $\frac{dP}{dz} = \Gamma \times 0$ which is multiplied by this

quantity which is 0. So, eventually we have dP/dz where P is a total power is 0 or the total power is conserved.

So, Manley-Rowe equation is nothing, but the conservation of total power or the total energy. So, this is a another representation to show that from Manley-Rowe relation I can or we can derive a important thing which is the conservation of total energy. So, whatever the three expression we derived so, this three expression are consistent with the conservation of energy.

And that is important and we to show that this is really conserved the total energy. So, even though the energies are exchanged between pump and signal and idler, but every time the energy governs that every time the total energies are remain conserved. Here we show that the Manley-Rowe equation for these three expressions are in such a way that they can conserve the total power or the total energy. So, conservation of energy is valid here for this 3 equation that we have derived for pump signal and the other and idler ok.

(Refer Slide Time: 17:01)

Parametric down conversion

A nonlinear crystal is used to split photon beams into pairs of photons that, in accordance with the law of conservation of energy and law of conservation of momentum

(SHG)

$\omega_3 \rightarrow \omega_2 + \omega_1$

$\hbar\omega_3 = \hbar\omega_2 + \hbar\omega_1$

$(\omega_3 = \omega_1 + \omega_2)$

Energy conservation

Momentum conservation

$\vec{k}^{(2\omega)}$

$\vec{k}^{(\omega)}$ $\vec{k}^{(\omega)}$

IIT KHARAGPUR NPTEL ONLINE CERTIFICATION COURSES Dr. Samudra Roy Department of Physics

So, now, we will go to the another thing that is parametric down conversion. So, here what we are doing that in nonlinear crystal used to split photon beams into pairs of photon that, in accordance with the laws of conservation of the energy and conservation of momentum; that means, we are launching 1 photon and this photon can splits and generate to other photons.

So, in general if I write in general way. So, omega is a photon. So, omega 3 and it is divided to 2 photon omega 2 plus omega 1. So, from 1 photon I can generate 2 photons, but the generation in such a way the generation should be in such a way that the loss of energy and momentum is conserved. So, what is the energy here total energy if h so, h cross omega 3 this is the energy of the omega 3. It is from this we are generating 2 photons.

So, the energy of the 2 photons is h cross omega 1 and h cross omega 2 and h cross omega 1. So that means, the energy according to the conservation of energy my omega 3 has to be equal to omega 1 plus omega 2 that is my 1 equation; is a conservation of energy equation.

(Refer Slide Time: 19:03)

Parametric down conversion

$\omega_3 = \omega_1 + \omega_2$
 $k_3 = k_1 + k_2$
 (SHG)

A nonlinear crystal is used to split photon beams into pairs of photons that, in accordance with the law of conservation of energy and law of conservation of momentum

Energy conservation

$2\omega = \omega + \omega$

Momentum conservation

$\vec{k}^{(2\omega)} = \vec{k}^{(\omega)} + \vec{k}^{(\omega)}$

IIT KHARAGPUR NPTEL ONLINE CERTIFICATION COURSES Dr. Samudra Roy Department of Physics

Now, for this same treatment from where were getting omega 3 is split into 2 photon omega 1 and omega 2; the momentum has to be conserved also. So, k 3 which is the momentum or the propagation vector has to be equal to k 1 plus k 2. This k 3 equal to k 1 plus k 2 is nothing, but the phase matching condition; this is another way to write the phase matching condition. So, this momentum and energy conservation is valid. What happened in under that condition, if we split 2 photons that or from 1 photon 2 photons are generated or 2 photon are merging to generate 1 photon that we try to understand.

So, here in the second harmonic generation process we find that for 2 photon is merging to generate 1 photon of frequency 2 omega and readily we can see that the energy and

momentum conservation are valid. Here in the next case what we try to do that we try to generate 2 photon of frequency ω , but we are generating that from 1 photon of frequency 2ω . This is some sort of frequency down conversion that we try to generate sub harmonics. So, energy conservation again this is a degenerate case $\omega_1 = \omega_2 = \omega$.

(Refer Slide Time: 20:34)

The slide is titled "Parametric down conversion" and is divided into two main sections. The top section, labeled "(SHG)", shows two input photons with frequency ω entering a box, and one output photon with frequency 2ω exiting. A handwritten note says $\omega_3 = \omega_1 + \omega_2$. To the right, text states: "A nonlinear crystal is used to split photon beams into pairs of photons that, in accordance with the law of conservation of energy and law of conservation of momentum". The bottom section shows a single input photon with frequency 2ω entering a box, and two output photons with frequency ω exiting. Below this are two diagrams: "Energy conservation" showing a vertical axis with a level at 2ω and two levels at ω , and "Momentum conservation" showing a horizontal axis with a vector $\vec{k}^{(2\omega)}$ and two vectors $\vec{k}^{(\omega)}$.

So, previously what I say that $\omega_3 = \omega_1 + \omega_2$. So, if $\omega_1 = \omega_2 = \omega$ then it is nothing, but the second harmonic generation. In the similar way, I can write that for degenerate case I can generate 2ω from 2ω I generate $\omega_1 = \omega_2 = \omega$ because, $\omega_1 = \omega_2 = \omega$ same right now. And a momentum conservation suggest that this is something like this which is nothing, but the collinear phase matching kind of stuff.

(Refer Slide Time: 21:15)

Parametric down-conversion

$2\omega \rightarrow \omega$

For $\Delta k = 0$,

$$\frac{dE_1}{dz} = i \frac{d\omega}{n_1 c} E_2 E_1^*$$
$$\frac{dE_2}{dz} = i \frac{d\omega}{n_2 c} E_1^2$$

Under no depletion approximation $E_2 = \text{cont}$ and also $E_1(0) = 0$.

$$\frac{d^2 E_1}{dz^2} = i \frac{d\omega}{n_1 c} E_2 \left(\frac{dE_1^*}{dz} \right)$$

IIT KHARAGPUR NPTEL ONLINE CERTIFICATION COURSES Dr. Samudra Roy Department of Physics

Now, the question is really it is possible to generate or not? It is really possible to generate. So, in parametric down conversion what we are trying to do from 2 omega to omega I want to generate; 2 equations should be in our hand and these 2 equation is this. This 2 equations the governing equation of the fundamental wave and second harmonics so, now I generate second harmonic two fundamental. So that means, I am generating E 1 in our case delta k is a phase matching, we considered the phase matching is already there; that means, the momentum conservation is already valid.

So, momentum conservation is valid, energy conservation is valid. So, now, our aim is to find out whether we can generate some kind of sub harmonic under this kind of condition or not. So, sub harmonic means try to find out the evolution of E 1. Under no depletion approximation E 2 is constant and E 1 is 0. So, what is going on here if I write, if I draw a picture here this picture should be something like this.

(Refer Slide Time: 22:21)

Parametric down-conversion

For $\Delta k = 0$,

$$\frac{dE_1}{dz} = i \frac{d\omega}{n_1 c} E_2 E_1^*$$

$$\frac{dE_2}{dz} = i \frac{d\omega}{n_2 c} E_1^2$$

Under no depletion approximation $E_2 = \text{const}$ and also $E_1(0) = 0$.

$$\frac{d^2 E_1}{dz^2} = i \frac{d\omega}{n_1 c} E_2 \left(\frac{dE_1^*}{dz} \right)$$

Handwritten notes on the slide:

- $z=0$
- $E_1(z=0) = 0$
- B.C.

Dr. Samudra Roy
Department of Physics

This is E_2 with frequency 2ω and try to generate here E_1 with frequency ω . The question is really it is possible to generate? This is at z equal to 0 so, at z equal to 0 what happened there is no wave of frequency ω . So, this quantity has to be 0. This is our boundary condition fine.

So, two condition we consider one is E_2 is constant and another is $E_1(0) = 0$. We have this expression in our hand so, what we do you make a second derivative to solve this equation. When you make a second derivative one equation will come as dE_1^*/dz , here E_2 is constant so, there will be no derivative of this term..

(Refer Slide Time: 23:34)

$$\frac{d^2 E_1}{dz^2} = i \frac{d\omega}{n_1 c} E_2 \left(-i \frac{d\omega}{n_1 c} E_2^* E_1 \right)$$

$$\frac{d^2 E_1}{dz^2} = \left(\frac{\omega d}{n_1 c} \right)^2 |E_2|^2 E_1$$

$$\gamma^2 = \left(\frac{\omega d}{n_1 c} \right)^2 |E_2|^2$$

$$\frac{d^2 E_1}{dz^2} = \gamma^2 E_1$$

$$\frac{dE_1}{dz} = i \frac{d\omega}{n_1 c} E_2 E_1^*$$

$$\frac{dE_2}{dz} = i \frac{d\omega}{n_2 c} E_1^2$$

Dr. Samudra Roy
Department of Physics

Once we have this, then the next thing is we just replace in terms of $d E_1^* / dz$; we replace because $d E_1 / dz$ already we know this is the value. So, I need to replace this minus i because complex conjugate of this will be $d E_1^* / dz$. So, it will be $d \omega n_1 c E_2^* E_1$; here should be star and this should be E_1 because I making a complex conjugate of that. So, I just replace this things here as I do and once I replace this thing here; then I can find the this i will remain $d \omega n_1 c d \omega n_1 c E_2 E_2^*$.

(Refer Slide Time: 24:41)

$$\frac{d^2 E_1}{dz^2} = i \frac{d\omega}{n_1 c} E_2 \left(-i \frac{d\omega}{n_1 c} E_2^* E_1 \right)$$

$$\frac{d^2 E_1}{dz^2} = \left(\frac{\omega d}{n_1 c} \right)^2 |E_2|^2 E_1$$

$$\gamma^2 = \left(\frac{\omega d}{n_1 c} \right)^2 |E_2|^2$$

$$\frac{d^2 E_1}{dz^2} = \gamma^2 E_1$$

$$\frac{dE_1}{dz} = i \frac{d\omega}{n_1 c} E_2 E_1^*$$

$$\frac{dE_2}{dz} = i \frac{d\omega}{n_2 c} E_1^2$$

Dr. Samudra Roy

So, I can write it in this way ωd divided by $n_1 c$ whole square of that and mode of E_2 square and E_1 . The next thing one can do is make this entire thing as a constant because ωd $n_1 c$ these are constant. And E_2 is a pulse here or E_2 is a field associated with the second harmonic or the frequency 2ω and from the beginning we considered this is very strong. So, we can consider this has a constant also.

So, that is why we write a constant here γ which is this. So, γ is ωd $n_1 c$ square and mode of E_2 square we write it as γ square. So, the total equation become simplified and we have in our hand is second order differential equation with the form $d^2 E_1$ divided by dz^2 is equal to $\gamma^2 E_1$. This is a second order differential equation and also we know what is the solution of that. So, what kind of solution we will have?

(Refer Slide Time: 25:59)

$E_1(z) = A \sinh(\gamma z) + B \cosh(\gamma z)$

Now at $z = 0$, $E_1(z = 0) = 0$; that means $B = 0$.

$E_1(z) = A \sinh(\gamma z)$

Again,

$E_1(0) = B = 0$

$$\left[\frac{dE_1}{dz} \right]_{z=0} = i \frac{\omega d}{n_1 c} E_2(0) E_1^*(0) = 0$$

$$\left[\frac{dE_1}{dz} \right]_{z=0} = A \gamma \cosh(\gamma z)|_{z=0} = A \gamma = 0$$

Dr. Samudra Roy

So, we will have a sin hyperbolic kind of solution or cos hyperbolic of solution. Eventually we have a exponential hyperbolic solution and this exponential hyperbolic solution one can write very easily with this sin and cos hyperbolic. So, this is a general solution. Now, if I put the boundary condition so, the boundary condition. suggest that E_1 is z equal to 0 because at the beginning there is no sub harmonic waves.

So, if I do then readily at if I put z equal to 0 then I readily can see that this is 0 and this is 1. So, we have B , but the entire thing is 0 means B equal to 0. So, $E_1(0)$ which is B

and this quantity is 0 ; that means, B is equal to 0. Once B is equal to 0 I can eliminate this term.

(Refer Slide Time: 27:06)

$E_1(z) = A \sinh(\gamma z) + B \cosh(\gamma z)$

Now at $z = 0$, $E_1(z = 0) = 0$; that means $B = 0$.

$E_1(z) = A \sinh(\gamma z)$

Again, $\frac{dE_1}{dz} \Big|_{z=0} = i \frac{\omega}{n_1 c} E_1^* E_2$

$$\left[\frac{dE_1}{dz} \right]_{z=0} = i \frac{\omega d}{n_1 c} E_2(0) E_1^*(0) = 0$$

$$\left[\frac{dE_1}{dz} \right]_{z=0} = A \gamma \cosh(\gamma z) \Big|_{z=0} = A \gamma = 0 \Rightarrow A = 0$$

So, we will have simply $A \sinh(\gamma z)$ as a solution of $E_1(z)$. Next thing is to find out A and in order to do that what we will do, we just make a derivative of this term. If I make a derivative we know that $\frac{dE_1}{dz}$ is $i \frac{\omega}{n_1 c} E_1^* E_2$ that was our equation. So, this quantity at $z = 0$ if I want to find then it will be $i \frac{\omega}{n_1 c} E_2$ at $z = 0$ and E_1^* at $z = 0$.

Now, E_1^* at $z = 0$ is 0 because I consider we considered there is no field. So, E_1 at $z = 0$ and E_1^* at $z = 0$ at the same thing here amplitude is not there or vanishing so, this quantity is 0. From here also we can find out $\frac{dE_1}{dz}$, if I do then I will have $A \gamma \cosh(\gamma z)$ at $z = 0$. So, at $z = 0$ $\cosh(\gamma z)$ become 1. So, we have $A \gamma = 0$ or from here we can see γ is a constant so, $A = 0$. Already we get $B = 0$ now; the next thing I get is $A = 0$. So, once we have $A = 0$; that means, the entire E_1 is vanished there is no E_1 .

(Refer Slide Time: 28:52)

Here $\gamma \neq 0$ so $A = 0$, which means $E_1(z) = 0$, so classically there will be no frequency down conversion where there is no input field containing ω frequency. That is without any *Quantum Noise* we cannot generate any sub-harmonics.

The diagram shows a box labeled $\chi^{(2)}$. An input arrow from the left is labeled 2ω and $E_1(\omega)$. An output arrow to the right is labeled ω and $E_1(2\omega) \neq 0$. The output arrow has a red 'X' over it and a red underline, indicating that classically this process does not occur.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Dr. Samudra Roy, Department of Physics

And that is interesting that here γ is not equal to 0 as I mentioned. So, A is equal to 0 which means $E_1(z) = 0$; that means, there should not be any so, the thing is that we will have 2ω here which is launched. This is the medium where $\chi^{(2)}$ is not equal to 0, but this medium suggests that there should not be any kind of ω field generations. So, ω field will not go to generate so that means, there will be no sub-harmonic generation.

But in general we find that the sub-harmonics are still generating; that means, if I launch 2ω , ω can be generated. So, classically we find that there is sub-harmonic generation is not possible unless we put some kind of very tiny amount of electric field here with field ω . So, I need some amount of ω . So, the boundary condition E_1 at $z = 0$ should not be 0 that is boundary condition we now put to generate some kind of sub-harmonic classically.

But quantum mechanically we can see that some kind of quantum noise should be there and because of this quantum noise there is a possibility that we can generate sub-harmonic. So, without any quantum noise it is not possible to generate. So, in the next class so, let me conclude here today. So, so far we are dealing with the sub-harmonic generation.

So, this is a parametric process; that means, I am launching 2ω and try to generate ω . And this process classically it is not possible in this process, we find that classically

it is not possible to find out any kind of sub harmonic waves. In order to generate sub harmonic waves what we need to do, there we need to put some kind of input of this sub harmonic field. And in the next class you will find that even if I put the input that may not be amplified.

So, there is a possibility that even if I put some kind of input value in terms of E_1 or the fundamental wave; so, it will not going to increase and it may be decrease depending on the phase, initial phase of the system. So, in the next class we will find out how the phase will be important here and this phase sensitive amplification and phase sensitive attenuation we will discuss in detail in the context of optical parametric amplification. So, with this note let me conclude here. So, in the so, see you in the next class and,

Thank you for your attention.
