Hello, we have been start working on BCS Theory, which we motivated from a first from a physical point of view and second from the famous calculation of Leon Cooper; where, he showed that a 2 electrons placed at the top of the Fermi level, just above the Fermi level and allowed to interact by a weak attractive interaction.

No matter how weak that interaction is that will form a bound state and that bound state has a negative energy of course, and that problem was solved we showed how to solve that problem. And the results are really remarkable that in such cases you will have 2 electrons forming a bound state and these bound states are in having a negative energy as all bound states too, negative energy bound state.

So, that led to the idea that the Fermi surface therefore, becomes unstable of against such pair formation and these pairs are called Cooper pairs. Nowadays, they are charged 2 E pairs and they conduct electricity because they have a charge. So, the actually that is a and as an aside

is that superfluid is a very similar state, but the super fluids do not have charge; whereas, superconductors the cooper pairs have a charge so that they carry current.

The way BCS theory was set up was a interesting because unlike in many cases, where 1 start nowadays does many body perturbation theory. In this case, what a Bardeen Cooper and Schrieffer did was that they just wrote down a wave function for the many body states which is a remarkable achievement, which is very rarely done that you are writing down an eigenstate for a problem, a many body wave function for a problem which constitutes 10 to the power 23 particles interacting with each other.

And that this worked beautifully was partly due to the reason that the coulomb interaction repulsive part was screened off and the attractive interaction worked at a large distance and in a very narrow range in frequency which is retarded interaction and it is very weak. So, that leads us to this theory of BCS and the so called BCS ground state.

(Refer Slide Time: 03:37)

The total energy reduction due to the pair collisions  $(\mathbf{k}, -\mathbf{k}) \rightarrow (\mathbf{k}', -\mathbf{k}')$  can be most easily calculated via the Hamiltonian  $H_{int}$ , which explicitly takes account of the fact that the "annihilation" of a pair  $(\mathbf{k}, -\mathbf{k})$  and the "simultaneous creation" of a pair  $(\mathbf{k}', -\mathbf{k}')$ , i.e. a scattering from  $(\mathbf{k}, -\mathbf{k})$  to  $(\mathbf{k}', -\mathbf{k}')$ , leads to an energy reduction of  $\epsilon_{\mathbf{k}\mathbf{k}'}$ .

The most general state of the pair  $(\mathbf{k}, -\mathbf{k})$

$$|\psi_{\mathbf{k}}\rangle = u_{\mathbf{k}}|0\rangle_{\mathbf{k}} + v_{\mathbf{k}}|1\rangle_{\mathbf{k}}$$

$u_{\mathbf{k}} = v_{\mathbf{k}}^2$  and  $1 - v_{\mathbf{k}} = u_{\mathbf{k}}^2$  are the probabilities that the pair state is occupied and unoccupied. The probability amplitudes are assumed to be real.

The ground state of the many body system of all cooper pairs can be approximated by the product of the state vectors of the single pairs

$$|\phi_{BCS}\rangle \approx \prod_{\mathbf{k}} [u_{\mathbf{k}}|0\rangle_{\mathbf{k}} + v_{\mathbf{k}}|1\rangle_{\mathbf{k}}]$$

Representation in  $k$  space of the occupying of an electron pair with wave vectors  $(\mathbf{k}, \mathbf{k}')$

Handwritten equation:  $|\phi_{BCS}\rangle = \prod_{\mathbf{k}} (u_{\mathbf{k}} |0\rangle_{\mathbf{k}} + v_{\mathbf{k}} |1\rangle_{\mathbf{k}})$

I have also mentioned that the BCS ground state as written here for example, this one is basically it is like a two level system which is you have a pair state which is either occupied or unoccupied. So, a pair state means 2 electrons occupying the minus k down plus k up kind of state simultaneously and forming a bound state and you can either occupy it or not occupy it with probabilities  $v_{\mathbf{k}} v_{\mathbf{k}}$  and  $u_{\mathbf{k}} u_{\mathbf{k}}$ .

So, this is a typical wave function that you write down for a two level system with two states and then of course, you can take a product of such states and that is what these people did. So, this product state as I mentioned just taking just take 2 values of  $k$  say 1 and 2 and you will see that this state is not a state with fixed number of particles. So, it is not an eigenstate of the number operator.

In fact, the Hamiltonian which BCS wrote down does not commute with the number operator. So that means, this state has all even number of electrons and that is what I showed. So, this state is basically 0 pair, 1 pair, 2 pair, 3 pair and so on and so forth. It contains all possible pair  $n$  by 2 possible pairs in it;  $n$  is the total number of electrons in the system. So, it is not a number eigen state.

If that has fundamental consequences which if we get time, we will mention and that is that what Anderson showed was that this wave function is actually a wave function for a it is a eigenstate for phase operator. So, phase is the phase of the function is the right quantum number is the well, the number is not a good quantum number; where, phase is the is the good quantum remember  $n$  and  $\phi$  if you remember your Heisenberg uncertainty  $n$  and  $\phi$  are the conjugate variables.

So, if  $n$  fluctuates enormously, then  $\phi$  becomes fixed and that is exactly what happens here ok.

(Refer Slide Time: 06:10)

This approximation amounts to a description of the many-body state in terms of non-interacting pairs, i.e., interactions between the pairs are neglected in the state vector. In the two-dimensional representation

$$|0\rangle_{\mathbf{k}} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}_{\mathbf{k}}, \quad |1\rangle_{\mathbf{k}} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}_{\mathbf{k}}$$

one can use the Pauli matrices

$$\sigma_{\mathbf{k}}^x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}_{\mathbf{k}}, \quad \sigma_{\mathbf{k}}^y = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}_{\mathbf{k}}$$

to describe the "creation" or "annihilation" of a Cooper pair. The operator

$$\sigma_{\mathbf{k}}^+ = \frac{1}{2}(\sigma_{\mathbf{k}}^x + i\sigma_{\mathbf{k}}^y)$$

transforms the unoccupied state  $|0\rangle_{\mathbf{k}}$  into the occupied state  $|1\rangle_{\mathbf{k}}$ , while

$$\sigma_{\mathbf{k}}^- = \frac{1}{2}(\sigma_{\mathbf{k}}^x - i\sigma_{\mathbf{k}}^y)$$

transforms the state  $|1\rangle_{\mathbf{k}}$  into  $|0\rangle_{\mathbf{k}}$ .

So, that is an aside. So, let us just go ahead and do the calculation that BCS did. So, they wrote down the I mean you can write down, they did not do it in this way, but you can write down a kind of spin algebra for excuse me for this kind of a system for two level systems that we mentioned earlier also and you write down in terms of say sigma x and sigma y which is sigma 1 and sigma 2 written here and you can define raising and lowering operator and these.

(Refer Slide Time: 06:42)

From these representations one can easily write

$$\sigma_{\mathbf{k}}^+ |1\rangle_{\mathbf{k}} = 0, \quad \sigma_{\mathbf{k}}^+ |0\rangle_{\mathbf{k}} = |1\rangle_{\mathbf{k}},$$

$$\sigma_{\mathbf{k}}^- |1\rangle_{\mathbf{k}} = |0\rangle_{\mathbf{k}}, \quad \sigma_{\mathbf{k}}^- |0\rangle_{\mathbf{k}} = 0.$$

The matrices  $\sigma_{\mathbf{k}}^+$  and  $\sigma_{\mathbf{k}}^-$  are formally identical to the spin operators. Their physical interpretation as "creation" and "annihilation operator" of Cooper pairs is however completely different.

Scattering from  $(\mathbf{k} \uparrow, -\mathbf{k} \downarrow)$  to  $(\mathbf{k}' \uparrow, -\mathbf{k}' \downarrow)$  is associated with an energy reduction by an amount  $\epsilon_{\mathbf{k}\mathbf{k}'}$ . In the simple BCS model of superconductivity this interaction matrix element  $\epsilon_{\mathbf{k}\mathbf{k}'}$  is assumed to be independent of  $\mathbf{k}, \mathbf{k}'$  i.e. constant.

We relate this to the normalization volume of the crystal,  $L^3$ , by setting it equal to  $\epsilon_0/L^3$ . The scattering process is described in the two-dimensional representation as annihilation of  $\mathbf{k}$  and creation of  $\mathbf{k}'$ . The operator that describe the corresponding energy reduction is thus found to be  $(\epsilon_0/L^3)\sigma_{\mathbf{k}}^+\sigma_{\mathbf{k}'}^-$ . The total energy reduction due to pair collisions  $\mathbf{k} \rightarrow \mathbf{k}'$  and  $\mathbf{k}' \rightarrow \mathbf{k}$  is given by summing over all collisions and may be expressed in operator terminology as

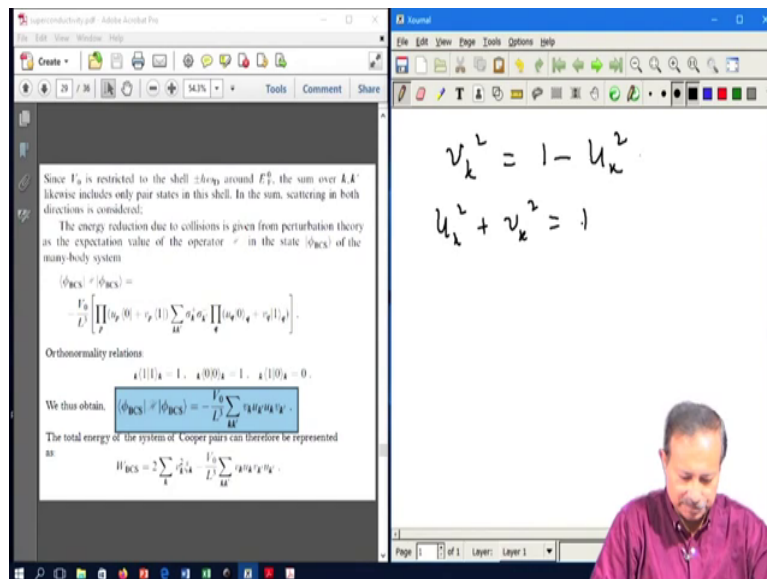

$$= -\frac{\epsilon_0}{L^3} \sum_{\mathbf{k}} \sum_{\mathbf{k}'} \frac{1}{2} (\sigma_{\mathbf{k}}^+\sigma_{\mathbf{k}'}^- + \sigma_{\mathbf{k}'}^+\sigma_{\mathbf{k}}^-) = -\frac{\epsilon_0}{L^3} \sum_{\mathbf{k}} \sigma_{\mathbf{k}}^+\sigma_{\mathbf{k}}^-$$

So, this is just straightforward algebra and then of course, you know that 1 is the highest occupied state. So, you cannot raise beyond 1. So, you will get 0. Similarly, if you raise from 0, you will get 1 and so on and so forth and you can choose a basis which is this and then, correspondingly the sigmas are the power 2 by 2 poly matrices.

Now, as we saw in the problem of cooper scattering from a one occupied k state which means a pair state to another k prime state is associated with an energy reduction. So, that is why the scattering takes place and that is what finally, reduces the energy and that is the  $V_{k k'}$ .

So, in the BCS model one then just writes down a Hamiltonian of this kind. I mean this is the energy reduction due to pair collision is then given by all such collisions all such scattering processes involving this  $V_{k k'}$  and involving all possible pairs k and k prime and that is exactly what this Hamiltonian does ok. And since, k and k prime are different you can commute them and you can write it in this fashion.

(Refer Slide Time: 07:59)

So, then we went ahead and we said that you now because the energies are so small compared to the other energy scales, just the you are allowed to do this calculation that you are trying to figure out the expectation value of. So, the scheme of things is just is to calculate this expectation value, which is the ground state energy. If you can find it out, of the Hamiltonian, in this basis in the psi BCS.

So, one basically finds out this energy and these remember these energies are very very small. So, you have to be careful and you have to do everything correctly ok. In this of course, this basis is interesting because it is very easy to calculate expectation values in this wave function. So, then use these orthonormality relations and you can immediately find out the expectation value of the Hamiltonian in this BCS state.

This is the scattering part the part that is in that involves  $V$ , so that is what you are doing. Now, the kinetic energy part is trivial, I mean it is just that to every pair has 2 electrons. So, it is the original 2 electron energies and the multiplied by the probability of  $v_k$  square and that the pair is occupied.

So,  $\psi_k$  into 2 multiplied by the probability of occupancy of the state and summed over all  $k$  in. So, this is all that one has to do here. But now of course, you have to remember these  $u_k$ 's and  $v_k$ 's are variational parameters. So, this is how all variational theories go as we did in several cases even that remember that hydrogen atom hydrogen molecule problem, we did the variational calculation. So, exactly same way.

The variational parameters here are of course, these probabilities  $u_k$  square and  $v_k$  square. So,  $u_k$ ,  $v_k$  are the variational parameters that you have to minimize with respect to and this  $W$  BCS is the energy that you will minimize with respect to  $u_k$  and  $v_k$ . But what is interesting is that remember we had this relation that  $v_k$  square equal to 1 minus  $u_k$  square.

So that means,  $u_k$  square plus  $v_k$  square equal to 1 which is which we basically is a statement of the fact that there the pair has to be either occupied or unoccupied. That means  $u_k$  and  $v_k$  are not 2 independent variables, there is only 1 variable that you need to minimize with respect to.

(Refer Slide Time: 11:12)

The BCS ground state at  $T = 0\text{K}$  of the system of Cooper pairs is given by the minimum,  $W_{\text{BCS}}$ , of the energy density  $W_{\text{BCS}}$ . By minimizing the equation as a function of the probability amplitudes  $u_k$  and  $v_k$  we obtain the energy of the ground state  $W_{\text{BCS}}$  and the occupation and non-occupation probabilities  $u_k = \sqrt{1 - v_k^2}$  and  $(-i v_k) = i u_k$ . The calculation is simplified by setting

$$u_k = \sqrt{1 - v_k^2} = \cos \theta_k,$$

$$v_k = \sqrt{1 - u_k^2} = \sin \theta_k,$$

which guarantees that

$$u_k^2 + v_k^2 = \cos^2 \theta_k + \sin^2 \theta_k = 1.$$

The minimizing is then with respect to  $\theta_k$ . The quantity to be minimized can be written

$$W_{\text{BCS}} = \sum_{\mathbf{k}} 2\epsilon_{\mathbf{k}} \cos^2 \theta_{\mathbf{k}} - \frac{1}{L^3} \sum_{\mathbf{k}} \cos \theta_{\mathbf{k}} \sin \theta_{\mathbf{k}} \cos \theta_{-\mathbf{k}} \sin \theta_{-\mathbf{k}}$$

$$= \sum_{\mathbf{k}} 2\epsilon_{\mathbf{k}} \cos^2 \theta_{\mathbf{k}} - \frac{1}{4L^3} \sum_{\mathbf{k}} \sin 2\theta_{\mathbf{k}} \sin 2\theta_{-\mathbf{k}}.$$

Handwritten on the whiteboard:

$$v_k^2 = 1 - u_k^2$$

$$u_k^2 + v_k^2 = 1$$

$$v_k = \cos \theta_k$$

$$u_k = \sin \theta_k$$

So, a convenient representation to do that is to convert in this kind of situations is to write down this as a cosine and sine. So, write  $v_k$  as cosine of  $\theta_k$  and then  $u_k$  has to be sine of  $\theta_k$  and then, you have only 1 variable to minimize which is  $\theta_k$  and that is exactly what we are doing here.

So, we write this as  $\psi_{\text{BCS}}$ ;  $W_{\text{BCS}}$  in terms of these variables right cosine  $\theta_k$  and sine  $\theta_k$  ok. So, once you do that, this is the result it is absolutely trivial to do. So, you can do it.

(Refer Slide Time: 11:57)

The condition for the minimum of  $W_{BCS}$  then reads

$$\frac{\partial W_{BCS}}{\partial \theta_k} = -2\zeta_k \sin 2\theta_k - \frac{V_0}{L^3} \sum_{k'} \cos 2\theta_k \sin 2\theta_{k'} = 0, \text{ or}$$

$$\zeta_k \tan 2\theta_k = -\frac{1}{2} \frac{V_0}{L^3} \sum_{k'} \sin 2\theta_{k'}.$$

We let

$$J = \frac{V_0}{L^3} \sum_{k'} \sin 2\theta_{k'} = \frac{V_0}{L^3} \sum_{k'} \sin \theta_{k'} \cos \theta_{k'},$$

$$E_k = \sqrt{\zeta_k^2 + J^2}$$

and obtain from standard trigonometry

$$\frac{\sin 2\theta_k}{\cos 2\theta_k} = \tan 2\theta_k \stackrel{::}{=} -J/\zeta_k,$$

$$\frac{2\theta_k \gamma_k = \sin 2\theta_k = J/E_k}{v_k^2 - u_k^2 = -\zeta_k/E_k}.$$

Handwritten on the whiteboard:

$$v_k^2 = 1 - u_k^2$$

$$u_k^2 + v_k^2 = 1$$

$$v_k = \cos \theta_k$$

$$u_k = \sin \theta_k$$

$$v_k^2 - u_k^2 = -\frac{\zeta_k}{E_k}$$

So, then, there is just one more step which is to minimize with respect to theta k and that gives you this relation and set it to 0. So, this gives me c k tan 2 theta k equal to minus half V 0 by L cube sum over all k prime sine 2 theta k prime. Then, you define delta. This is just the definition at the moment that this variable, we called this quantity which is k independent of course, because all k's are k's are summed here is called a delta.

Then, E k is a basically c k square plus delta square right. And from standard trigonometry, so let us just go back one more page. So, using this and of course, this is another definition you are using ok. So, you are going to calculate the W BCS finally, after finding out what the right theta k is. So, let us use these two definitions.

This is very standard definition; delta k and E k and then, just go ahead the go ahead and do the calculations. See this is tan 2 theta k is then minus delta by epsilon k and this to u k v k is sin 2 theta k is delta by E k and then, this relation is very important. The last one v k square minus u k square equal to minus c k by E k. This is what you will get. So, in terms of delta and E, capital E k you can write down your u k and v k from these two relations ok, the last two relations.

(Refer Slide Time: 14:09)

The slide on the left contains the following text and figure:

Thus the occupation probability,  $u_k = v_k^2$ , of a pair state  $(k\uparrow, -k\downarrow)$  in the BCS ground state at  $T = 0$  K is given by

$$u_k = v_k^2 = \frac{1}{2} \left( 1 - \frac{\xi_k}{E_k} \right) = \frac{1}{2} \left( 1 - \frac{\xi_k}{\sqrt{\xi_k^2 + \Delta^2}} \right)$$

The figure shows a plot of Probability  $w_k$  versus Electron energy  $\xi_k$ . The solid line represents  $w_k = v_k^2$  at  $T = 0$ , and the dashed line represents the Fermi function at  $T = T_c$ . The energy axis has markers at  $-\Delta$ ,  $0$ , and  $\Delta$ .

The whiteboard on the right shows the following handwritten formulas:

$$v_k^2 = \frac{1}{2} \left( 1 - \frac{\xi_k}{E_k} \right)$$

$$u_k^2 = \frac{1}{2} \left( 1 + \frac{\xi_k}{E_k} \right)$$

And that is exactly what is done  $v_k$  square is so that gives me  $v_k$  square equal to half 1 minus  $\xi_k$  by  $E_k$  and immediately I know what  $u_k$  square will be because they have to sum up to give me 1. So,  $u_k$  square equal to half into 1 plus  $\xi_k$  by  $E_k$  so, that is the these are the 2 values. Here, the  $v_k$  square is plotted at  $T$  equal to 0. It almost mimics the Fermi function at  $T$  equal to  $T_c$  and it is deviates from this vertical fall within a region of minus  $\Delta$  plus  $\Delta$ .

(Refer Slide Time: 15:06)

The slide on the left contains the following text and equations:

The energy of the superconducting BCS ground state is obtained as

$$W_{BCS}^0 = \sum_{\mathbf{k}} \xi_{\mathbf{k}} (1 - \xi_{\mathbf{k}}/E_{\mathbf{k}}) - L^3 \frac{\Delta^2}{V_0}$$

The condensation energy of the superconducting phase is obtained by subtracting from  $W_{BCS}^0$  the energy of the normal conducting phase, i.e., the energy of the Fermi-sea without the attractive interaction  $W_n^0 = \sum_{\mathbf{k}} \xi_{\mathbf{k}}$

$$W_{BCS}^0 = 2 \sum_{\mathbf{k}} (1 - u_{\mathbf{k}}^2) \xi_{\mathbf{k}} + 2 \sum_{\mathbf{k}} v_{\mathbf{k}}^2 \xi_{\mathbf{k}} - L^3 \frac{\Delta^2}{V_0}$$

$$= 2 \sum_{\mathbf{k}} \xi_{\mathbf{k}} - 2 \sum_{\mathbf{k}} u_{\mathbf{k}}^2 \xi_{\mathbf{k}} + 2 \sum_{\mathbf{k}} v_{\mathbf{k}}^2 \xi_{\mathbf{k}} - L^3 \frac{\Delta^2}{V_0}$$

Here the first term is exactly  $W_n^0$ . Going from the sum in  $\mathbf{k}$ -space to an integral  $(L^{-3} \sum_{\mathbf{k}} \rightarrow \int d\mathbf{k}/(4\pi^2))$ , after integration one obtains

$$(W_{BCS}^0 - W_n^0)/L^3 = -\frac{1}{2} N(0) \Delta^2$$

The whiteboard on the right shows the following handwritten formulas with checkmarks:

$$v_k^2 = \frac{1}{2} \left( 1 - \frac{\xi_k}{E_k} \right) \checkmark$$

$$u_k^2 = \frac{1}{2} \left( 1 + \frac{\xi_k}{E_k} \right) \checkmark$$

So, now that we have we found out this these variables  $u_k$  and  $v_k$  parameters the  $\psi$  BCS you can calculate in the ground state. So, we have found out  $u_k$  and  $v_k$  and the right hand side as I wrote down and of course, it is written here also  $v_k^2$  is this one and then of course,  $u_k^2$  is this one.

And now, we of course, showed that  $v_k^2$  follows the Fermi function more or less we and there is a drop within the region  $\pm \Delta$ . So, now what we have is the W BCS and in the ground state. So, energy of the BCS ground states ground state for that Hamiltonian that we wrote down and that energy can be now written down and one can do all kinds of things that one does this is very standard.

So, let me not get into it. See the first term here  $2 \int_0^{k_F} \epsilon_k$ , this term if you remember, this is just the energy of the electron, the Fermi sea up to the Fermi sea the electron gas that we started with. So, and these 2 is taking care of the spin; the 2 spins per momentum per state  $k$ .

So, and then  $\epsilon_k$  is the energy sum over all  $k$ 's below  $k_F$  is the original the energy which is the energy of the Fermi sea without the attractive interaction; without that  $V$  term at all. So, this was the original energy. So, whatever gain you have is you have to have over this. So, the total energy has to be less than this sum. So, that is what one finds out and you can see that this is negative.

(Refer Slide Time: 17:11)

Thus, for finite  $J$ , there is always a reduction in energy for the superconducting state, whereby  $J$  is a measure of the size of the reduction.

The decisive role of the parameter  $J$  is clear from the following: The first excitation state above the BCS ground state involves the breaking up of a Cooper pair due to an external influence. Here an electron is scattered out of  $(\mathbf{k})$  leaving behind an unpaired electron in  $(-\mathbf{k})$ . In order to calculate the necessary excitation energy, we rewrite the ground state energy  $H_{\text{BCS}}^0$  as follows:

$$H_{\text{BCS}}^0 = \sum_{\mathbf{k}} \xi_{\mathbf{k}} (1 - v_{\mathbf{k}}^2 / E_{\mathbf{k}}) - \frac{J^2 J^2}{V_0}$$

$$= \sum_{\mathbf{k}} E_{\mathbf{k}} (v_{\mathbf{k}}^2 - v_{\mathbf{k}}^2) - \sum_{\mathbf{k}} E_{\mathbf{k}} (v_{\mathbf{k}}^2 - v_{\mathbf{k}}^2) - \frac{J^2 J^2}{V_0}$$

$$= 2 \sum_{\mathbf{k}} E_{\mathbf{k}} v_{\mathbf{k}}^2 v_{\mathbf{k}}^2 + \sum_{\mathbf{k}} E_{\mathbf{k}} (v_{\mathbf{k}}^2 (1 - v_{\mathbf{k}}^2) - v_{\mathbf{k}}^2 (v_{\mathbf{k}}^2 - v_{\mathbf{k}}^2)) - \frac{J^2 J^2}{V_0}$$

$$= J \sum_{\mathbf{k}} v_{\mathbf{k}}^2 v_{\mathbf{k}}^2 - \frac{J^2 J^2}{V_0} + \sum_{\mathbf{k}} E_{\mathbf{k}} v_{\mathbf{k}}^2 (v_{\mathbf{k}}^2 - 1 - v_{\mathbf{k}}^2)$$

$$= -2 \sum_{\mathbf{k}} E_{\mathbf{k}} v_{\mathbf{k}}^2$$

Handwritten equations on the whiteboard:

$$v_{\mathbf{k}}^2 = \frac{1}{2} \left( 1 - \frac{\xi_{\mathbf{k}}}{E_{\mathbf{k}}} \right) \checkmark$$

$$u_{\mathbf{k}}^2 = \frac{1}{2} \left( 1 + \frac{\xi_{\mathbf{k}}}{E_{\mathbf{k}}} \right) \checkmark$$

And so that is about it that you need to know. These algebra you can do at home and this is not difficult, but this is not something that you have to remember, in the sense that you know how to calculate it and you know now that there is a gain in energy. So, that is about it.

(Refer Slide Time: 17:31)

If  $(\mathbf{k}', -\mathbf{k}')$  is occupied, i.e.  $v_{\mathbf{k}'}^2 = 1$ , then the first excited state  $H_{\text{BCS}}^1$  is achieved by breaking up the pair, i.e.  $v_{\mathbf{k}'}^2 = 0$ , and therefore

$$H_{\text{BCS}}^1 = -2 \sum_{\mathbf{k}'} E_{\mathbf{k}'} v_{\mathbf{k}'}^2$$

The necessary excitation energy is the difference between the energies of the initial and final states

$$\Delta E = H_{\text{BCS}}^1 - H_{\text{BCS}}^0 = 2E_{\mathbf{k}} = 2\sqrt{\xi_{\mathbf{k}}^2 + J^2}$$

The first term in the square-root,  $\xi_{\mathbf{k}}^2$ , describes the kinetic energy of the two electrons "scattered" out of the Cooper pair. Since  $\xi_{\mathbf{k}} = \hbar^2 \mathbf{k}^2 / 2m = E_{\mathbf{k}}^0$ , this can be arbitrarily small, i.e. the excitation requires a minimum finite energy

$$\Delta E_{\text{min}} = 2J$$

The excitation spectrum of the superconducting state contains a gap of  $2J$ , which corresponds to the energy required to break up a Cooper pair.

Handwritten equations on the whiteboard:

$$v_{\mathbf{k}}^2 = \frac{1}{2} \left( 1 - \frac{\xi_{\mathbf{k}}}{E_{\mathbf{k}}} \right) \checkmark$$

$$u_{\mathbf{k}}^2 = \frac{1}{2} \left( 1 + \frac{\xi_{\mathbf{k}}}{E_{\mathbf{k}}} \right) \checkmark$$

Diagram showing energy levels with a gap of  $2\Delta$  and the word "insulator" written below.

So, let us try to find out the BCS energy which is basically the this and therefore, this is the first excited state in BCS; excitation of the energy. This is the BCS ground state and this is the first excited state energy and you just subtract these two and you will get the energy of the

first excited state. And we will I will show you in a few slides, how the density of states is now arranged and then, you will see that there is a gap in the density of states.

So, this energy actually this  $\Delta E$  tells you that there is a gap because  $c_k$  minimum of  $c_k$  can be 0; whereas, even then you will still have a gap which is  $2\Delta$  and that is exactly what it shows. So, the excitation requires a minimum finite energy of  $2\Delta$ . So that means, the spectrum is such the density of states are such that you have these 2 sets of states and there is a gap of a  $2\Delta$ ; this is  $2\Delta$ .

So, it is very different from the Fermi sea. So, a gap has now opened up where there was originally a Fermi surface Fermi level where there was the Fermi level. So, basically that means, that there is no Fermi surface anymore. So, this gap is basically the energy that we have to supply to break a Cooper pair and that is the; that is the consequence of the BCS theory and remember, I mentioned that the essential picture that BCS wanted to get was that there has to be a gap in the spectrum.

Because there are already experimental evidences there from thermal conductivity and so on that there exists a gap in the spectrum. There must be a gap in the spectrum. But then, the difference from a semiconductor for example, or an insulator is just enormous because this is not a picture of a semiconductor or an insulator, where these states are single particle states and these are the states, where you fill in like this in semiconductors.

In insulator, what you do is that you just keep on filling these states. Here, you of course, fill these states, but these states are not the semiconducting states. I mean these are not a single particle states which are just obtained by a single particle calculation.

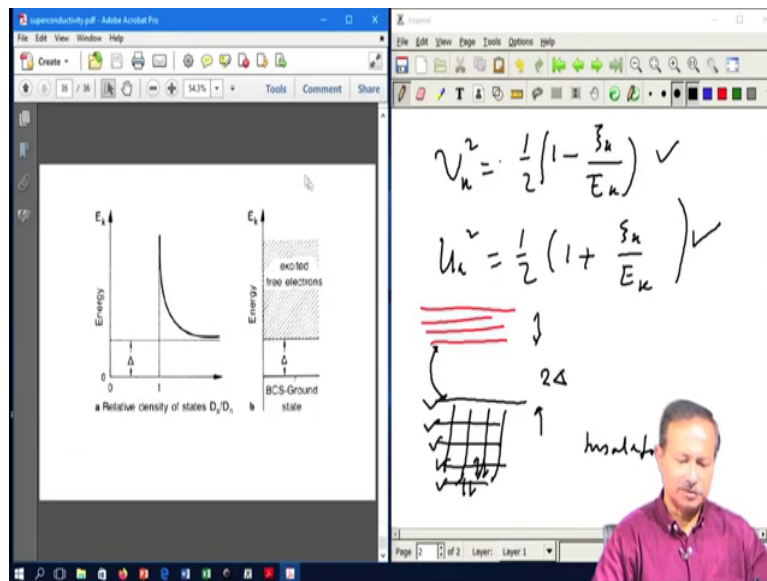

So, these are many body states and this picture here is very very different from the picture of a semiconductor. Because here, all the states are filled up that is it; whereas, you want to excite of course, you have to break a pair and the pair goes here. So, these this is like this these are single particle excitations of course, but the nature of this states is very very different from the picture that we give when we did band structure calculation.

There we had obtained we just had a rigid band bands were there, we form the bands irrespective of the number of electrons. We always did it for 1 electron actually and then, we

calculated the bands available, the states available for the single electrons and then filled them up. Here, it is very different. Here these those states that you had in the Fermi sea that you had is no longer stable. So, you have completely obliterated those states, but the number of states counts have to be the same.

So, that has to be the same and that is what leads to this excitation leads to the density of states for a BCS superconductor.

(Refer Slide Time: 22:05)

So, what we did so far let me just recap a bit we have done something very very different from what we have so far done in our all our calculations. This is the first time, we are encountering in a free electron gas in an electron gas interacting via a very weak coulomb interaction, the weak attractive interaction, we found out a many body ground state. By many body ground state, I mean that if you take this ground state  $\psi_{BCS}$  equal to  $\prod_k u_k + v_k a_{k\uparrow} a_{-k\downarrow}$ .

Then you can see that this state contains all the particles, I mean it has all the it is a superposition of 0, 1, 2, 3 up to n by 2 pairs and that means, that this is a you in one shot you are writing down the ground state. And that that was the assumption of BCS that we do have a ground state and we know what it is and this represents the ground state and that is what it is.

(Refer Slide Time: 23:36)

This approximation amounts to a description of the many-body state in terms of non-interacting pairs, i.e. interactions between the pairs are neglected in the state vector. In the two-dimensional representation

$$|0_k\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix}_k, \quad |1_k\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix}_k$$

one can use the Pauli matrices

$$\sigma_k^x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}_k, \quad \sigma_k^y = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}_k$$

to describe the "creation" or "annihilation" of a Cooper pair. The operator

$$\sigma_k^+ = \frac{1}{2}(\sigma_k^x + i\sigma_k^y)$$

transforms the unoccupied state  $|0_k\rangle$  into the occupied state  $|1_k\rangle$ , while

$$\sigma_k^- = \frac{1}{2}(\sigma_k^x - i\sigma_k^y)$$

transforms the state  $|1_k\rangle$  into  $|0_k\rangle$ .

$$|\phi_{BCS}\rangle = \prod_k (u_k |0_k\rangle + v_k |1_k\rangle)$$

And then, the question was how do I find its energy and we sort of did a trick in the sense that because it is a there are only 2 levels a for every k value either it is occupied or it is unoccupied. So, 2 energy states. Then, we can write down the whole thing in terms of spin operators. These are pseudo spin operators in some sense and we can create and annihilate a cooper pair and that representation is a this right. It is exactly like s plus and s minus for each k state and that is what we did.

(Refer Slide Time: 24:21)

From these representations one can easily write

$$\sigma_k^+ |1_k\rangle = 0, \quad \sigma_k^+ |0_k\rangle = |1_k\rangle,$$

$$\sigma_k^- |1_k\rangle = |0_k\rangle, \quad \sigma_k^- |0_k\rangle = 0.$$

The matrices  $\sigma_k^+$  and  $\sigma_k^-$  are formally identical to the spin operators. Their physical interpretation as "creation" and "annihilation operator" of Cooper pairs is however completely different.

Scattering from  $(\mathbf{k}, -\mathbf{k})$  to  $(\mathbf{k}', -\mathbf{k}')$  is associated with an energy reduction by an amount  $V_{\mathbf{k}\mathbf{k}'}$ . In the simple BCS model of superconductivity this interaction matrix element  $V_{\mathbf{k}\mathbf{k}'}$  is assumed to be independent of  $\mathbf{k}, \mathbf{k}'$  i.e. constant.

We relate this to the normalization volume of the crystal,  $L^3$ , by setting it equal to  $V_0/L^3$ . The scattering process is described in the two-dimensional representation as annihilation of  $\mathbf{k}$  and creation of  $\mathbf{k}'$ . The operator that describes the corresponding energy reduction is thus found to be  $-(V_0/L^3)\sigma_{\mathbf{k}}^+\sigma_{\mathbf{k}'}^-$ . The total energy reduction due to pair collisions  $\mathbf{k} \rightarrow \mathbf{k}'$  and  $\mathbf{k} \rightarrow \mathbf{k}$  is given by summing over all collisions and may be expressed in operator terminology as

$$E = -\frac{1}{L^3} V_0 \sum_{\mathbf{k}} \sum_{\mathbf{k}'} (\sigma_{\mathbf{k}}^+ \sigma_{\mathbf{k}'}^- + \sigma_{\mathbf{k}}^- \sigma_{\mathbf{k}'}^+) = -\frac{V_0}{L^3} \sum_{\mathbf{k}, \mathbf{k}'} \sigma_{\mathbf{k}}^+ \sigma_{\mathbf{k}'}^-$$

$$|\phi_{BCS}\rangle = \prod_k (u_k |0_k\rangle + v_k |1_k\rangle)$$

$$E = -\frac{V_0}{L^3} \sum_{\mathbf{k}, \mathbf{k}'} \sigma_{\mathbf{k}}^+ \sigma_{\mathbf{k}'}^-$$

$$\bar{\mathbf{k}} \leftarrow \bar{\mathbf{k}'}$$

And then, what we did was that we just carried on and we just completed the algebra here, just wrote down what the algebra is and using that what we tried to do was to calculate. First, we wrote down the interaction part of the Hamiltonian which is the V part which is  $V_0$  by  $L$  cube  $\sigma_{\mathbf{k}} + \sigma_{\mathbf{k}'}$  minus. So, what it does is that it destroys a pair at  $\mathbf{k}'$  and creates a pair at  $\mathbf{k}$ .

So, that is all it does. So, this term right. So, it takes a pair from  $\mathbf{k}'$  to  $\mathbf{k}$  ok. So, and of course, there is a Hermitian conjugate because that is ensured by this sum over  $\mathbf{k}$   $\mathbf{k}'$ , that term is also there. So, with this because you are summing over all that term will already be there.

(Refer Slide Time: 25:45)

The image shows a presentation slide on the left and a handwritten note on the right. The slide text includes:

Since  $\Psi_0$  is restricted to the shell  $\pm k_F$  around  $F_0^+$ , the sum over  $k, k'$  likewise includes only pair states in this shell. In the sum, scattering in both directions is considered.

The energy reduction due to collisions is given from perturbation theory as the expectation value of the operator  $\lambda_V$  in the state  $|\phi_{BCS}\rangle$  of the many-body system

$$\langle \phi_{BCS} | \lambda_V | \phi_{BCS} \rangle = -\frac{V_0}{L^3} \left[ \prod_{\mathbf{k}} (|u_{\mathbf{k}}|^2 + |v_{\mathbf{k}}|^2) \sum_{\mathbf{k}'} u_{\mathbf{k}'} v_{\mathbf{k}'} \prod_{\mathbf{k}} (|u_{\mathbf{k}}|^2 + |v_{\mathbf{k}}|^2) \right]$$

Orthonormality relations:  $u_{\mathbf{k}}(1)u_{\mathbf{k}} = 1, u_{\mathbf{k}}(0)u_{\mathbf{k}} = 1, u_{\mathbf{k}}(1)v_{\mathbf{k}} = 0$ .

We thus obtain:  $\langle \phi_{BCS} | \lambda_V | \phi_{BCS} \rangle = -\frac{V_0}{L^3} \sum_{\mathbf{k}} u_{\mathbf{k}} v_{\mathbf{k}} u_{\mathbf{k}} v_{\mathbf{k}}$ .

The total energy of the system of Cooper pairs can therefore be represented as:

$$E_{BCS} = 2 \sum_{\mathbf{k}} \epsilon_{\mathbf{k}} u_{\mathbf{k}}^2 v_{\mathbf{k}}^2 - \frac{V_0}{L^3} \sum_{\mathbf{k}} u_{\mathbf{k}} v_{\mathbf{k}} u_{\mathbf{k}} v_{\mathbf{k}}$$

The handwritten note on the right shows:

$$|\phi_{BCS}\rangle = \prod_{\mathbf{k}} (u_{\mathbf{k}} |0\rangle_{\mathbf{k}} + v_{\mathbf{k}} |1\rangle_{\mathbf{k}})$$

$$\lambda_V = -\frac{V_0}{L^3} \sum_{\mathbf{k}, \mathbf{k}'} \sigma_{\mathbf{k}}^+ \sigma_{\mathbf{k}'}^-$$

$\mathbf{k} \leftarrow \mathbf{k}'$

$$\langle \phi_{BCS} | \lambda_V | \phi_{BCS} \rangle$$

And then, what we did is that we just calculated the expectation value. We calculated psi ok. So, what we calculated is this thing psi BCS in this H, in this H V psi BCS and then, we just added the energy for the number of pairs. So, energy twice epsilon  $\mathbf{k}$  is the energy of the pair times  $v_{\mathbf{k}}^2$  is its probability of being there ok.

(Refer Slide Time: 26:17)

The BCS ground state at  $T = 0\text{K}$  of the system of Cooper pairs is given by the minimum,  $W_{\text{BCS}}$ , of the energy density  $W_{\text{BCS}}$ . By minimizing the equation as a function of the probability amplitudes  $u_k$  and  $v_k$  we obtain the energy of the ground state  $W_{\text{BCS}}$  and the occupation and non-occupation probabilities  $u_k = \sqrt{w_k}$  and  $(1 - w_k) = v_k^2$ . The calculation is simplified by setting

$$u_k = \sqrt{w_k} = \cos \theta_k,$$

$$v_k = \sqrt{1 - w_k} = \sin \theta_k,$$

which guarantees that

$$u_k^2 + v_k^2 = \cos^2 \theta_k + \sin^2 \theta_k = 1.$$

The minimizing is then with respect to  $\theta_k$ . The quantity to be minimized can be written

$$W_{\text{BCS}} = \sum_k 2t_k \cos^2 \theta_k - \frac{t_k^2}{U} \sum_k \cos \theta_k \sin \theta_k \cos \theta_k \sin \theta_k$$

$$= \sum_k 2t_k \cos^2 \theta_k - \frac{t_k^2}{U} \sum_k \sin 2\theta_k \sin 2\theta_k.$$

So, that gives us a the total energy and then of course, since only 1 variable is relevant because  $u_k$  and  $v_k$  are connected. So, we converted into a 1 variable minimization by writing this. So, it is like a rotation so, in the  $u_k, v_k$  space and. So, basically a rotation in the you can look at it in the rotation of the pair and not pair 0 and 1 in this space, in the bases between the bases.

So, you choose the right direction of the linear combination between 0 and 1. So, that is what we do I mean when we want to diagonalize a Hamiltonian. So, that is what we did we basically found out the right combination of 0 and 1  $k$  states and the correspondingly, we defined something called  $\Delta_k$  and  $E_k$  and so on and we finally, found out the values of  $u_k$  and  $v_k$  which is given here.

This is  $v_k$  square and  $u_k$  square is just 1 minus  $v_k$  square. So then, we actually found out that there is a condensation energy, in the sense that the energy has now become less than the original Fermi sea energy and that means, there is a new ground state.

(Refer Slide Time: 27:45)

The energy of the superconducting BCS ground state is obtained as

$$W_{\text{BCS}} = \sum_{\mathbf{k}} \xi_{\mathbf{k}} (1 - \xi_{\mathbf{k}}/E_{\mathbf{k}}) - L^3 \frac{\Delta^2}{V_0}$$

The condensation energy of the superconducting phase is obtained by subtracting from  $W_{\text{BCS}}$  the energy of the normal conducting phase, i.e., the energy of the Fermi-sea without the attractive interaction  $W_{\text{FS}} = \sum_{\mathbf{k}, \sigma} \xi_{\mathbf{k}}$

$$W_{\text{BCS}} = 2 \sum_{\mathbf{k}, \mathbf{k}_k} (1 - \xi_{\mathbf{k}}^2) \xi_{\mathbf{k}} + 2 \sum_{\mathbf{k}, \mathbf{k}_k} \xi_{\mathbf{k}}^2 \xi_{\mathbf{k}} - L^3 \frac{\Delta^2}{V_0}$$

$$= 2 \sum_{\mathbf{k}, \mathbf{k}_k} \xi_{\mathbf{k}} - 2 \sum_{\mathbf{k}, \mathbf{k}_k} \xi_{\mathbf{k}}^2 \xi_{\mathbf{k}} + 2 \sum_{\mathbf{k}, \mathbf{k}_k} \xi_{\mathbf{k}}^2 \xi_{\mathbf{k}} - L^3 \frac{\Delta^2}{V_0}$$

Here the first term is exactly  $W_{\text{FS}}$ . Going from the sum in  $\mathbf{k}$ -space to an integral  $(L^{-3} \sum_{\mathbf{k}} \rightarrow \int d\mathbf{k}/4\pi^2)$ , after integration one obtains

$$(W_{\text{BCS}} - W_{\text{FS}})/L^3 = -\frac{1}{2} N(0) \Delta^2$$

And this ground state is lower in energy than the original Fermi sea ground state ok. So, far so good and then, what we found that we found the excitation energy of the first excited state over the ground state energy and that has this form and there is a difference between the two which gives us the first the gap in the excitation and that is this excitation.

(Refer Slide Time: 28:16)

Relative density of states  $D_s/D_n$

BCS-Ground state

excited free electrons

$$E_k = \sqrt{\xi_k^2 + \Delta^2}$$

$$D_s(E_k) dE_k = P(\xi_k) d\xi_k$$

$$P(\xi_k) \approx P(E_F)$$

$$\frac{d\xi_k}{dE_k}$$

What is interesting is that now you can actually calculate the. So, this is the new spectrum  $E_k$  equal to  $c k$  square plus  $\Delta$  square.  $\Delta$  has no  $k$  dependence in this theory. There are

theories where  $\Delta$  is also  $k$  dependent. We will mention them when if you have time. Now, what you can do is that you can just calculate the density of states which is I will show in detail, which is which basically comes from this relation that  $D_s(E_k) dE_k$  must be equal to must be preserved.

So, the density of states cannot be eaten up, number of states cannot be eaten up. So, that should be equal to the original  $\rho(E_k) dE_k$ . So, this relation and then, what you do is that you just replace this  $\rho(E_k)$  by it is Fermi level value. This generally written as  $\rho_0$  or  $\rho(E_F)$  whatever you want here we are using  $\rho(E_F)$ . So, let me use that  $E_F$  and you can do it yourself to find out.

So, all you have to do sorry  $\rho$ , I am sorry this. So, all you have to do is to find this derivative  $d\epsilon_k / dE_k$  and you will find that you have a density of states of this kind which is divergent and which there is no state between in the gap in this region from minus  $\Delta$  to plus  $\Delta$ . So, that is the gap, that is the excitation.

All the states in the negative energy are filled up the positive energy states states are empty and there is a gap the in the density of states and that. So, these are single particle density of states that we are talking about. So, these are excitations and then, the excitation has a gap which is  $2\Delta$  and that density of states is divergent at  $E$  equal to  $\Delta$ . So, so there is a pile-up of density of states.

So, you move density of states away from a Fermi level and pile them up at a plus  $\Delta$  and minus  $\Delta$ . Of course, that is like a this old Fermi old Fermi sea states are not there. These are new excitations. These excitations are excitations over the BCS ground state and their spectrum has this pile up at plus  $\Delta$  and minus  $\Delta$  and that has fundamental consequences.

Two things; one is this gap and the other is there is a pileup. There is a divergence at plus  $\Delta$  and minus. So, these things are very important and these have experimental ramifications which we will discuss in the next class.
