Modes (Cont.)
Lecture - 30
Modes in an optical fiber

Hello student to the course of Physics of Linear and Non-Linear Optical Waveguides. Today, we have lecture number 30. And, today we will going to study a very important topic, which is Modes in an Optical Fiber.

(Refer Slide Time: 00:27)

So, today we are going to learn modes for a step index fiber. So, far we are dealing with the modes for planar waveguides. So, today we will going to study the modes for step index fiber.

So, let me first draw, the structure of the optical fiber. We had a core part surrounded by a cladding. This is the structure geometrical structure of a fiber, where the refractive index profile is this first step index.

So, this is n_1 , n_2 and the refractive index is n_1 , this is n_2 . So, we have a cylindrical symmetry of this geometry. And, we are going to use this cylindrical symmetry in the Maxwell's equation to find out the modes that is all.

(Refer Slide Time: 02:17)

Diagram of a step-index optical fiber with core refractive index n_1 and cladding refractive index n_2 .

Field $\psi(r, \phi, z, t) = \psi_a(r, \phi) e^{i(\beta z - \omega t)}$

Wave Eqn $\nabla_{r\phi z}^2 \psi = \frac{n^2(r, \phi)}{c^2} \frac{\partial^2 \psi}{\partial t^2}$

$\nabla_{r\phi z}^2 = \nabla_{r\phi}^2 + \partial_z^2$ $\partial_z^2 \equiv \frac{\partial^2}{\partial z^2}$

$(\nabla_{r\phi}^2 + \partial_z^2) \psi = \frac{n^2}{c^2} \frac{\partial^2 \psi}{\partial t^2} = -\frac{n^2 \omega^2}{c^2} \psi$

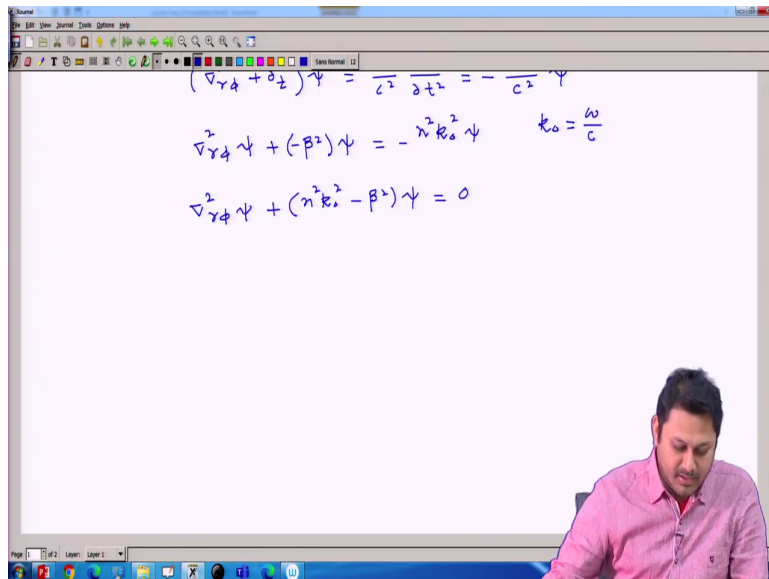

So, for this kind of system if I write the field, it should be $\psi(r, \phi, z, t)$ it should be a function of r, ϕ, z , because I am dealing with now a cylindrical symmetry. It should be divided into 2 part 1 is ψ_a , which is dealing with the r, ϕ part and a propagation part as usual with $\beta z - \omega t$.

So, I have r ϕ dependency here and z and t dependency in the exponential term. So, this is a definition or this is a form of an optical field, that is going to propagate inside the fiber, which has a cylindrical symmetry. Now, we have the wave equation, which is of the form this. Now, here this operator the Laplacian operator, I should write in cylindrical coordinate that is something we need to take care.

So, if I write this operator it should be r ϕ plus this is a shorthand notation. So, if I write this; that means, I am eventually doing the partial derivative with respect to z like this second order partial derivative. Now, if I going to operate these things over here. So, I will have this quantity $\frac{\partial^2}{\partial z^2} \psi$, because I know what is my ψ .

I can write it as minus of n^2 , ω^2 divided by c^2 and then ψ . Because, when I make a double derivative of this given field, the term here sitting should come out the ω should come out as minus $i \omega$ twice I should have a negative sign. And, it simply n^2 , ω^2 divided by c^2 and then ψ .

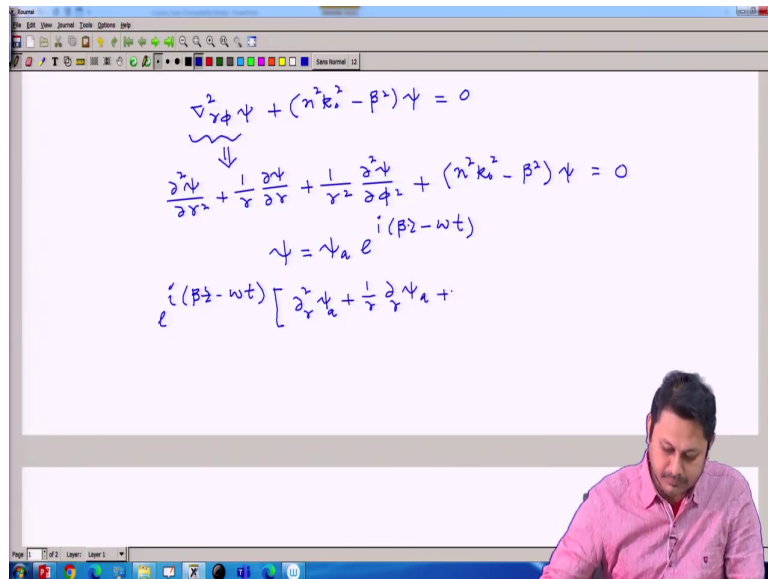

(Refer Slide Time: 05:55)

$$\begin{aligned}(\nabla_{\mathbf{r}}^2 + \epsilon_0) \psi &= \frac{1}{c^2} \frac{\partial^2 \psi}{\partial t^2} = -\frac{1}{c^2} \psi \\ \nabla_{\mathbf{r}}^2 \psi + (-\beta^2) \psi &= -n^2 k_0^2 \psi \quad k_0 = \frac{\omega}{c} \\ \nabla_{\mathbf{r}}^2 \psi + (n^2 k_0^2 - \beta^2) \psi &= 0\end{aligned}$$

And, the first two part is simply; this portion I have a second order derivative with respect to z and I know this is my field.

So, if I do it should be minus of beta square psi is equal to minus of n square k_0 square psi, where my k_0 is omega divided by c , free space propagation, free space propagation constant or wave vector. So, eventually I have this, this is the equation I am right now having. Now, I will I can write this part in x in a expanded form.

(Refer Slide Time: 07:11)

$$\nabla_r^2 \psi + (n^2 k_0^2 - \beta^2) \psi = 0$$

$$\Downarrow$$

$$\frac{\partial^2 \psi}{\partial r^2} + \frac{1}{r} \frac{\partial \psi}{\partial r} + \frac{1}{r^2} \frac{\partial^2 \psi}{\partial \phi^2} + (n^2 k_0^2 - \beta^2) \psi = 0$$

$$\psi = \psi_a e^{i(\beta z - \omega t)}$$

$$e^{i(\beta z - \omega t)} \left[\frac{\partial^2 \psi_a}{\partial r^2} + \frac{1}{r} \frac{\partial \psi_a}{\partial r} + \dots \right]$$

So, in expanded form it should be $\frac{\partial^2 \psi}{\partial r^2} + \frac{1}{r} \frac{\partial \psi}{\partial r} + \frac{1}{r^2} \frac{\partial^2 \psi}{\partial \phi^2} + (n^2 k_0^2 - \beta^2) \psi = 0$, plus this is only this portion is this one, plus the rest of the term that we already derived ok. Now, ψ is something like $\psi_a e^{i(\beta z - \omega t)}$, already we defined that. So, if I put this value here, then you can see $e^{i(\beta z - \omega t)}$ does not have any dependency of r and ϕ and here it is only ψ_a .

So, I can write this equation in terms of ψ_a . So, it should be simply $e^{i(\beta z - \omega t)}$ plus, whatever, I have.

(Refer Slide Time: 09:01)

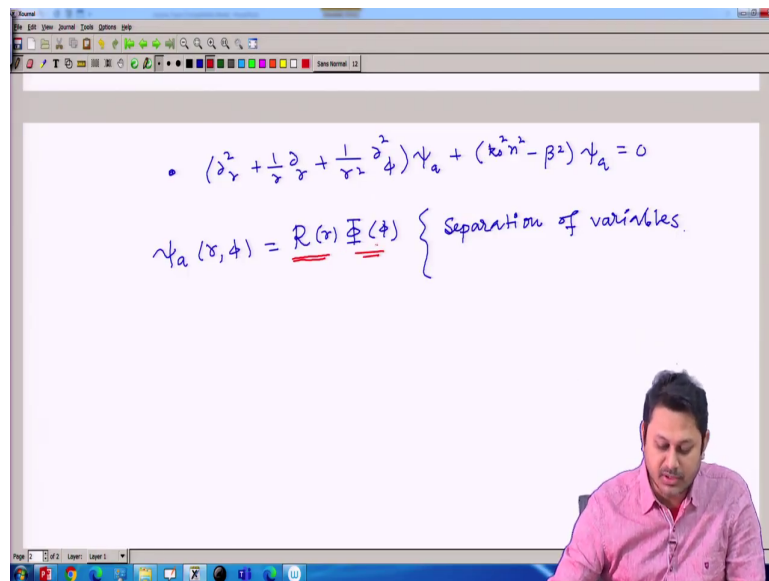

$$\frac{\partial^2 \psi}{\partial r^2} + \frac{1}{r} \frac{\partial \psi}{\partial r} + \frac{1}{r^2} \frac{\partial^2 \psi}{\partial \phi^2} + (k_0^2 - \beta^2) \psi = 0$$

$$\psi = \psi_a e^{i(\beta\phi - \omega t)}$$

$$e^{i(\beta\phi - \omega t)} \left[\frac{\partial^2 \psi_a}{\partial r^2} + \frac{1}{r} \frac{\partial \psi_a}{\partial r} + \frac{1}{r^2} \frac{\partial^2 \psi_a}{\partial \phi^2} \right] + e^{i(\beta\phi - \omega t)} (k_0^2 - \beta^2) \psi_a = 0$$

So, simply this term and this term will cancel out. And, eventually we have this ok.

(Refer Slide Time: 09:57)

$$\bullet \left(\partial_r^2 + \frac{1}{r} \partial_r + \frac{1}{r^2} \partial_\phi^2 \right) \psi_a + (k_0^2 n^2 - \beta^2) \psi_a = 0$$
$$\psi_a(r, \phi) = \underline{R(r)} \underline{\Phi(\phi)} \quad \left\{ \text{Separation of variables.} \right.$$

This is the expression; I have now right now. Well, I can now make a standard procedure which is called the separation of variable, that it is a function of r and ϕ . So, I can make it as a function of R r and big ϕ ϕ , which is called the separation of variables. I am making a separation of variables of that.

If I now have the separation of variable by making a function of R and ϕ like this and put this equation put this solution in the equation whatever we have. Then it is easy to show that I will have an equation like this.

(Refer Slide Time: 11:39)

$\psi_a(r, \phi) = \underline{R(r)} \underline{\Phi(\phi)}$ } separation of variables.

$$\frac{1}{R} \left[r^2 \frac{d^2 R}{dr^2} + r \frac{dR}{dr} + r^2 (k_0^2 n^2 - \beta^2) R \right] = -\frac{1}{\Phi} \frac{d^2 \Phi}{d\phi^2} = l^2 \text{ (say)}$$

Radial eqn
(R eqn) $r^2 \frac{d^2 R}{dr^2} + r \frac{dR}{dr} + [r^2 (k_0^2 n^2 - \beta^2) - l^2] R = 0$ ① ✓

Azimuthal eqn
(Φ eqn) $\frac{d^2 \Phi}{d\phi^2} + l^2 \Phi = 0$ ② ✓

This is equation with respect to R and in the right hand side I can have an equation with respect to phi only. Now, the left hand side of the equation is now as a function of R and the right hand side is a function of phi only.

Now, these two are equal; that means; obviously, they should be equal to some constant and I write this constant as l^2 . I write this in as a l^2 . Because just after few minutes you are going to find, that it will form a very well known differential equation.

If, I write this constant as l^2 only for that, because it can in principle it can be any constant. So, I write this constant in spatial form to have a spatial differential equation in our hand.

So, now I have the radial equation; that means, the equation related to r as $r^2 \frac{d^2 R}{dr^2} + r \frac{dR}{dr} + R(k_0^2 r^2 - \beta^2) = 0$. This is my left hand side I multiply this R here.

So, then put it back and then I am having this equation. So, this is the equation radial equation I am having. On the other hand the Azimuthal equation or ϕ equation, this is R equation. So, the ϕ equation should be something like this, $\frac{d^2 \phi}{d\phi^2} + l^2 \phi = 0$.

So, now I have 2 equation in my hand, this is the radial equation and this is the ϕ equation or Azimuthal equation. And, if I solve this 2 equation, then I can have the value of R and ϕ . And if I have the value of R and ϕ , then I can eventually have the value of ψ , which is the field distribution. Well, now I need to put something some condition, because in our case we have the step index fiber.

(Refer Slide Time: 15:59)

$$= -\frac{1}{\Phi} \frac{\partial^2 \Phi}{\partial r^2} = l^2 \text{ (Sng)}$$

Radial eqn
 (R eqn)
$$r^2 \frac{d^2 R}{dr^2} + r \frac{dR}{dr} + [r^2 (k_0^2 n^2 - \beta^2) - l^2] R = 0 \quad (1) \checkmark$$

Azimuthal eqn
 (Φ eqn)
$$\frac{d^2 \Phi}{d\phi^2} + l^2 \Phi = 0 \quad (2) \checkmark$$

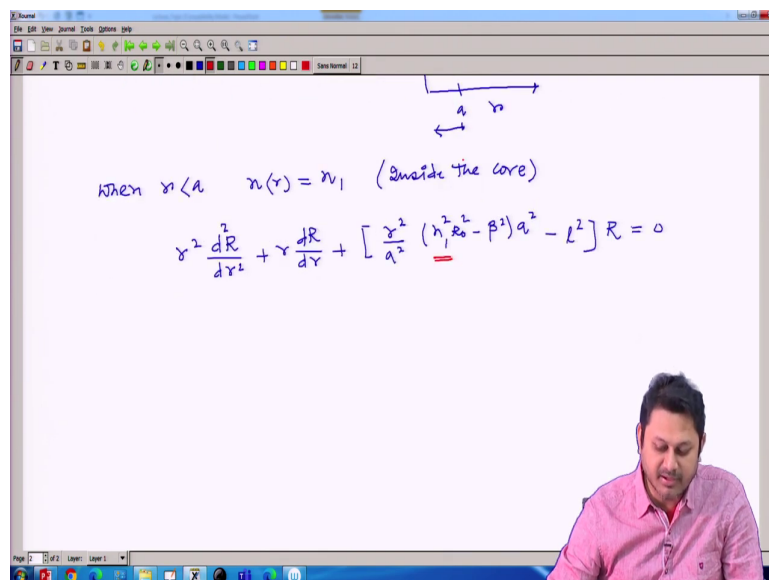

For step index fiber

Diagram: A graph of refractive index $n(r)$ versus radius r . The refractive index is constant at n_1 for $r \leq a$ and drops to n_2 for $r > a$. The core radius is labeled a .

So, I we have so, let me write it for step index fiber, what is the geometry of the step index fiber. So, if I now ok, let me draw in a more correct manner, because, now I am dealing with r so, beta to remove that this portion. And, so this is the refractive index as a function of r , this is my r , and this is a , this distance is a , which is the core part.

And, the refractive index is n_1 here and n_2 here. So, for step index fiber, this is the refractive index profile. So, once we know this is the refractive index profile I will going to put this information here in this equation.

(Refer Slide Time: 17:13)

So, when r is say less than a , function of $n(r)$ is simply n_1 a constant so; that means, this is inside the core. So, inside the core region I have this and I will put this into equation. And, if I put this into the radial equation it should be simply this. Now, I write here this term in this way, note it. I will put the n_1 here, because my I know in this equation, this n is now replaced by n_1 .

And, I write this r square multiplied by $k_0^2 n^2$ minus β^2 as r square divided by a square, and then I multiplied another a square here. There is a specific reason for that it will make my calculation a little bit simpler.

(Refer Slide Time: 18:59)

$$r^2 \frac{d^2 K}{dr^2} + r^2 \frac{dK}{dr} + \left[\frac{r^2}{a^2} - l^2 \right] K = 0$$

$$U = a(k_0^2 n_1^2 - \beta^2)^{1/2}$$

$$r^2 \frac{d^2 R}{dr^2} + r^2 \frac{dR}{dr} + \left[\frac{r^2 U^2}{a^2} - l^2 \right] R = 0$$

Now, we introduce a variable, a parameter, a u which is a into k_0 square, n_1 square minus β square. Note it U is a constant and a dimensionless quantity, so, better to write it is to the power half. So, this is something which is dimensionless. And, if I now write this equation in terms of U , then I should have this.

So, $r^2 \frac{d^2 R}{dr^2} + r^2 \frac{dR}{dr} +$ this portion you can see this is my U square. So, I can write it as $r^2 \frac{d^2 R}{dr^2} + r^2 \frac{dR}{dr} + \left[\frac{r^2 U^2}{a^2} - l^2 \right] R = 0$.

(Refer Slide Time: 20:33)

$$r^2 \frac{d^2 R}{dr^2} + r^2 \frac{dR}{dr} + \left[\frac{r^2 U^2}{a^2} - l^2 \right] R = 0$$

$$\frac{rU}{a} \rightarrow x \quad r = \frac{x a}{U}$$

$$\frac{dR}{dr} = \frac{dR}{dx} \frac{dx}{dr} = \frac{U}{a} \frac{dR}{dx}$$

$$\frac{d^2 R}{dr^2} = \frac{U^2}{a^2} \frac{d^2 R}{dx^2}$$

This quantity $r U$ divided by a we write it as x . I rescale it as x , then my r becomes simply x multiplied by $a U$. So, my $d R / d x$ should be equal to a by U . So, $d R / d r$, so this is a variable of r , now I change this variable to x . So, this quantity I can now write as using the chain rule as this, which is U by a ok, here it should be a smaller.

So, it should be U by a $d R / d x$. In the similar way, if I write the second derivative with respect to R , then it should be simply U square divided by a square $d^2 R / d x^2$. So, this transformation I have this is one transformation this is another, which I will going to put in this main equation. If I put everything into the main equation instead of r I put $x a$ divided by U , this double derivative with respect to small r I put this value and so on.

(Refer Slide Time: 22:49)

$$x^2 \frac{a^2}{u^2} \cdot \frac{d^2 R}{dx^2} + x \frac{a}{u} \cdot \frac{dR}{dx} + (x^2 - l^2)R = 0$$

$$\textcircled{1} \quad x^2 \frac{d^2 R}{dx^2} + x \frac{dR}{dx} + (x^2 - l^2)R = 0$$

Bessel's diff. eqn

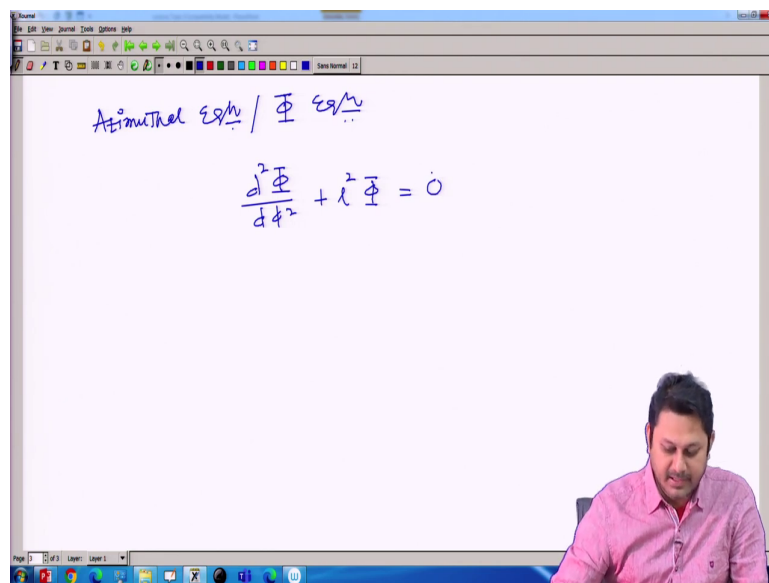

If I do, then I will going to have something like $x^2 a^2$ divided by U^2 . Then, U^2 by a^2 $d^2 R / dx^2$ plus $x a$ by U , then U by a , dR / dx , I am writing all the term explicitly, so, that you can understand what is going on here. And, x^2 divided by.

So, this is the equation I am having after transferring everything in terms of x . So, you can see this $U^2 a^2$ U^2 , a^2 , a by U , U by a this term will going to cancel out and I will have a very well known equation in my hand.

This is a very well known differential equation, and I believe by that time most of you have already recognized this differential equation, this is the Bessel's equation. After putting all this effort, I find the radial equation can be represented in terms of Bessel equation. So, the solution once you have this Bessel's differential equations, Bessel's differential equation.

Once, we have the Bessel's differential equation after putting all these variable and all these terms, then the next thing is will be simpler because we know what is the solution. So, we are going to use this solution directly, because now the solution of the differential equation of the radial part is known that is. So, let me write is this equations equation 1, another part is still there, which is the Azimuthal equation.

(Refer Slide Time: 25:33)

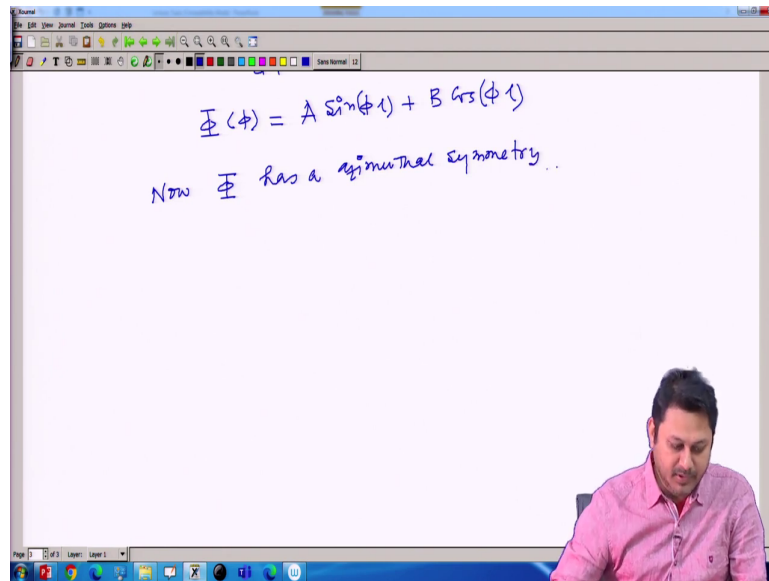

Azimuthal eqn / Φ eqn

$$\frac{d^2 \Phi}{d\phi^2} + \lambda^2 \Phi = 0$$

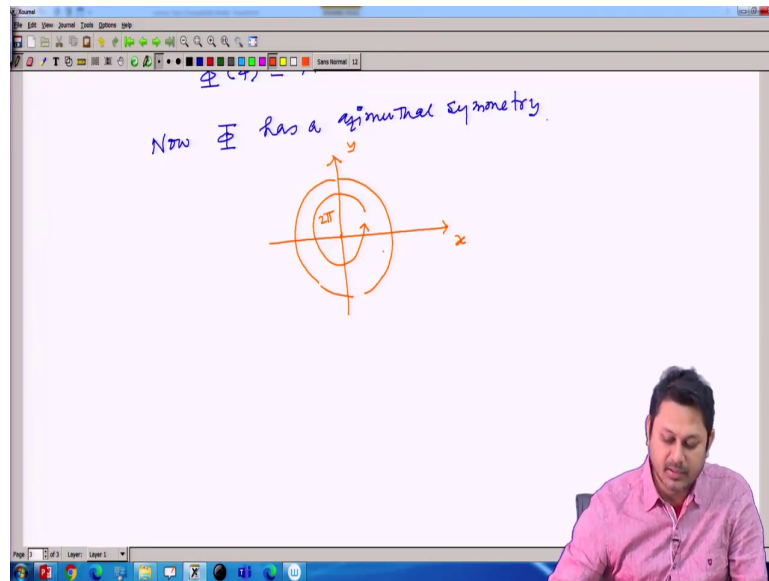

So, let me go back to my Azimuthal equation or my phi equation. This equation is little bit simpler and easy to solve. Because I know the structure of this differential equation and this is this, readily I have the solution and if I write the solution it should be a sinusoidal solution.

(Refer Slide Time: 26:11)

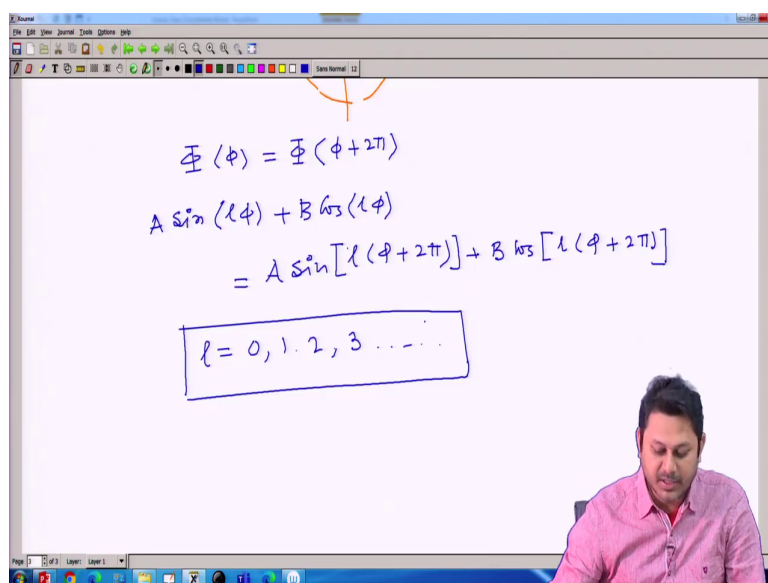

So, it is a function of small ϕ and I can write it as a constant A , then $\sin \phi$ plus another constant $B \cos$ of ϕ . You can note that this equation has a ϕ symmetry. So, when now ϕ has a azimuthal symmetry, what is the meaning of azimuthal symmetry? So, if I look carefully through the fiber structure.

(Refer Slide Time: 27:17)

So, the core part if I draw the core part. So, this is the fiber core x and y . And, whatever the solution I have here if I go to 2π if I make a round of 2π , then the solution will remain unchanged.

(Refer Slide Time: 27:55)

$$\Phi(\phi) = \Phi(\phi + 2\pi)$$
$$A \sin(l\phi) + B \cos(l\phi) = A \sin[l(\phi + 2\pi)] + B \cos[l(\phi + 2\pi)]$$
$$l = 0, 1, 2, 3, \dots$$

So; that means, ϕ of ϕ should be equal to ϕ of ϕ plus 2π . So; that means, A of $\sin l$ ϕ plus B of $\cos l$ ϕ , should be equal to A of $\sin l$ ϕ plus 2π plus B of \cos . And, it should be, it should be the same thing once we have l is equal to say integer $0, 1, 2, 3$ and so on.

If, the l s are integer, then this ϕ symmetry will follow. So, I have a very important information from this set, that l has to be the integer value having $1, 2, 3, 4$. It is restricted to some integer value, discrete integer value, it is not a continuous if this is not a constant with continuous values, it is a discrete values and this discrete values are $0, 1, 2$. So, eventually l is a integer.

Now, I do not have much time to you know solve this radial equation, the next part is I will going to solve this radial equation. So, in the next class we will start from this Bessel's

differential equation and try to solve, the equation try to put the solution of the equation which are the Bessel solutions. And, put certain boundary condition to find out that, what should be the form of exact solutions. So, with this note I would like to conclude here.

So, thank you for your attention and see you in the next class for the solutions.
