**Dispersion, Ray Path Constant**

Hello student to the course of Physics of Linear and Non-Linear Optical Waveguides. Today, we have lecture 9. And today we will going to cover the Detailed Calculation of the Dispersion, and a new concept called Ray Path Constant.

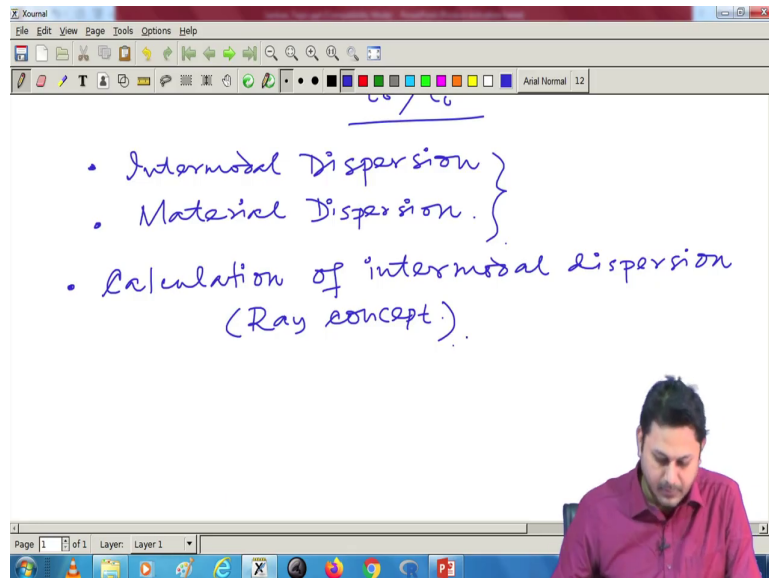

(Refer Slide Time: 00:40)

So, let me write it down, today we have lecture number 9. So, we were discussing about dispersion in the last class, and mentioned that when an optical pulse is propagating through a

dispersion medium, it encounter a dispersion and as a result there is a temporal broadening. So, this is  $t$ ; this is  $t$ . So, if I have  $t_0$  as a width here, this width becomes say  $t_0'$ , where  $t_0'$  is greater than  $t_0$ . And in the communication, this is a problem, these things is a problem. So, we will going to discuss that as well.

(Refer Slide Time: 02:07)

But today we will going to calculate the dispersion in terms of so there are two kind of dispersion we discuss; one is intermodal dispersion, and another was material dispersion. So, we can calculate the intermodal dispersion using the Ray concept. So, let us do that today first. Calculation of intermodal dispersion, and we will going to use the Ray concept.

(Refer Slide Time: 03:36)

So, let us first draw the structure of the waveguide like this. This is the axis of the fiber core. This is  $n_1$  – refractive index; this is  $n_2$ , this is  $n_2$  – refractive index, where  $n_1$  refractive index is greater than  $n_2$ . And if I launch a light here, let us make a different color, you will experience a total internal reflection like this, and hit here. Say this point is A, this point is B, this is C. This point says N, because I am going to use this point.

So, what essentially we will going to calculate here? The Ray a concept, this is the Ray that is passing by. This length is  $d$ . So, the time that we will going to take the ray a A, B, C and some other ray that we going to calculate. And we find there is a time lag between these two ray paths.

And this time lag is essentially the value of the dispersion in Ray concept. So, we will going to find first the time lag of these two rays. First we calculate the time taken by a arbitrary ray

coming from point A to C with this path ABC. So, this angle is  $\phi$  suppose this angle has to be  $\phi$ , because this is a total internal reflection is taking place at that point A.

Similarly, this is  $\phi$  as well. So, now, I can calculate few things. So, first thing, we can see here from this ABC this structure, this is a symmetric kind of structure that AB – the length AB is equal to BC. This is the first condition I can find from the simple geometrical structure. This angle is also  $\phi$ .

Now, what is  $\sin \phi$ ?  $\sin \phi$  is AN divided by AB from triangle ABN. So, this information I have beforehand. And now we calculate AB is now AN [music] divided by  $\sin \phi$ . In the similar way, I can write BC is equal to NC divided by  $\sin \phi$ . This from, this is from another triangle NCB; from NCB I can write the similar thing.

(Refer Slide Time: 08:36)

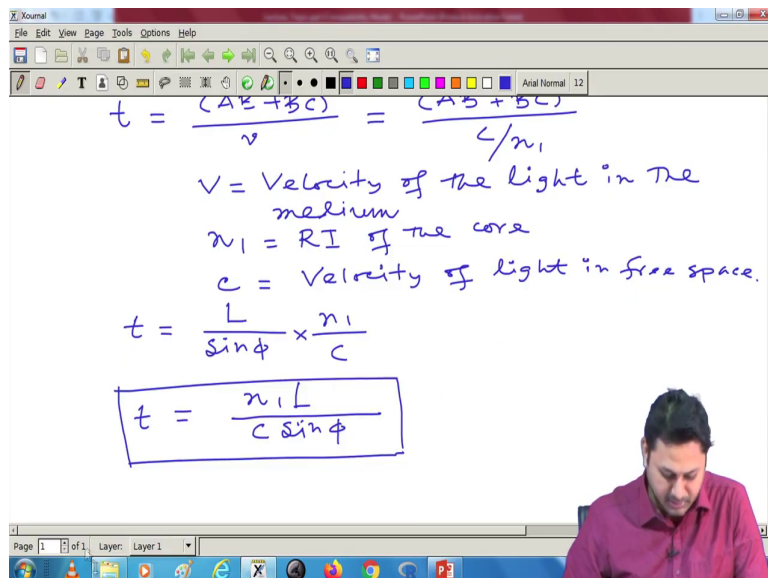

$$AB = \frac{AN}{\sin \phi} \quad BC = \frac{NC}{\sin \phi}$$
$$AB + BC \Rightarrow \text{The path.}$$
$$AB + BC = \frac{AN + NC}{\sin \phi} = \frac{L}{\sin \phi}$$

Now, what is AB plus BC? This is the path that is travelling by the light. So, this is the path that is travelling by this ray. Now, I can write this AB plus BC in terms of sin phi because I need to find out the relationship with this angle, whatever the angle it is making phi with the distance. So, AB plus BC is equal to AN plus NC divided by sin phi.

What is AN plus NC? This is the length of the fiber. Whatever the length it is travelling this is a length of that amount and this length suppose it is L. So, this is this length the straight line length for the point AC. However, the ray is travelling through this path with a reflection.

So, if it goes to a straight line, then it will going to take a smaller amount of time. It is quite obvious. But since the ray is passing through this, this internal reflection, it will take a little bit lot I mean longer time because it is travelling a larger amount of path. So, AN plus NC as I mentioned it is the length of the fiber. So, I can write L divided by L divided by sin phi. Now, I need to find out what is the time it is it with this fellow, there is no minus sign.

(Refer Slide Time: 11:09)

$$t = \frac{AB + BC}{v} = \frac{AB + BC}{c/n_1}$$

$v$  = Velocity of the light in the medium  
 $n_1$  = RI of the core  
 $c$  = Velocity of light in free space.

$$t = \frac{L}{\sin \phi} \times \frac{n_1}{c}$$
$$t = \frac{n_1 L}{c \sin \phi}$$

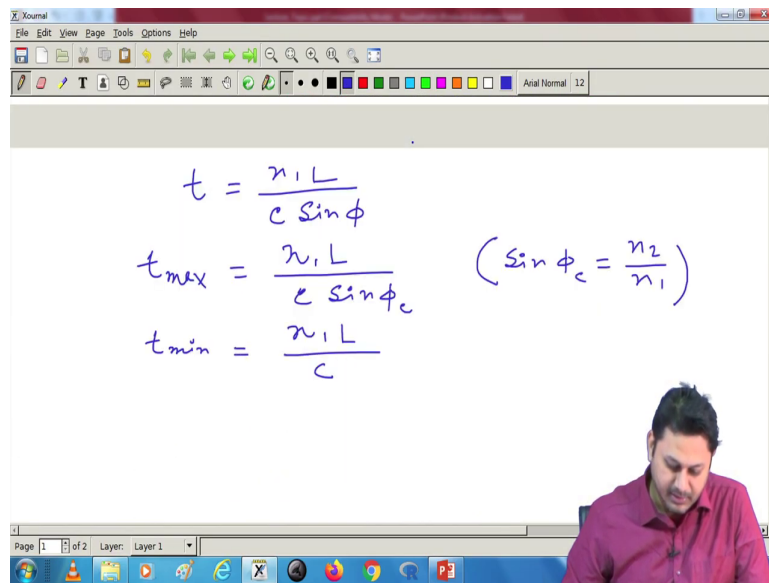

So,  $t$  that is the time that should take the path from go to A to B point through this A to C point through this reflection should be AB plus BC whole divided by the velocity. And we know the velocity inside a medium of refractive index  $n$  can be written as  $C$  divided by  $n_1$ , because  $n_1$  is a refractive index and  $C$  is a velocity of light.

So, here  $V$  is a velocity of the ray of the in velocity of the light rather in the medium;  $n_1$  is the refractive index of the core; and  $C$  here is the velocity of light in free space in free space. See eventually my  $t$  becomes if I now replace AB plus BC which I already calculated here AB plus BC is equal to  $L$  divided by  $\sin \phi$ , it should be simply  $L$  divided by  $\sin \phi$  multiplied by  $n_1$  divided by  $c$ .

So,  $n_1 L$  divided by  $C \sin \phi$ . This is expression a general expression of the time I have when the ray is propagating as a length  $L$  of the fiber, and then having an angle  $\phi$ . So, this

ray having an angle phi here is moving from A to C with a reflection at the point B. And if I calculate the amount of time it will going to take is  $n_1 L$  divided by  $C \sin \phi$ . So, if now I change  $\sin \phi$ , so obviously this time will going to change and that I need to calculate next.

(Refer Slide Time: 14:49)

$$t = \frac{n_1 L}{c \sin \phi}$$

$$t_{\max} = \frac{n_1 L}{c \sin \phi_c} \quad \left( \sin \phi_c = \frac{n_2}{n_1} \right)$$

$$t_{\min} = \frac{n_1 L}{c}$$

So, we have the general time the path going to take is  $n_1 L$  divided by  $C \sin \phi$ . Now, I can calculate the maximum amount of time a ray can take. And it will going to take if you look carefully to the figure here, the maximum if theta, if phi increases, if phi increases, then if phi increases, then what happened?

At some point, it should be it should be 90 degree, and the ray will simply pass with a linear distance  $L$  without having any kind of any kind of reflection. But if theta decreases, then I can see  $\sin \theta$  will going to decrease. And when  $\sin \theta$  is decreasing, the  $t$  will increase.

So, what is the, what is the minimum value we can have for  $\sin \theta$  should give us the maximum value of the  $t$  – the path? So, this minimum value of  $\sin \theta$  for total internal reflection we all know that it is the critical angle that it will have, so  $\sin \phi_c$ . When we have  $\sin \phi_c$ , the left hand side  $t$  will be a maximum value. And in terms of refractive index, I can also write  $\sin \phi_c$  as  $\sin \phi_c$  equal to  $n_2$  divided by  $n_1$  using the Snell's law.

So, that I know. And what is  $t$  minimum?  $t$  minimum is straight forward. It is  $n_1 L$  divided by  $c$  when  $\sin \phi$  is  $\phi_c$   $\phi$  is  $\pi/2$  as I mentioned. And if I calculate very simple way that the ray is travelling in a straight line path, the ray which is so let me draw which ray you will going to take this time, it will be clear.

So, I make it another color. So, the ray that is passing through this simply this path following this path, we will going to take a time, here I can write  $t$  for this ray – this green ray will be  $n_1 L$  divided by  $c$ . So, these two ray is having a  $t_{\max}$  and  $t_{\min}$ , obviously, there is some time difference between these two ray.

So, when we start from one single point, so one ray will going to take this time –  $t_{\max}$ , and another ray will take  $t_{\min}$ . So, there is a maximum difference between these two rays which is basically the measurement of the dispersion in this problem.

(Refer Slide Time: 18:20)

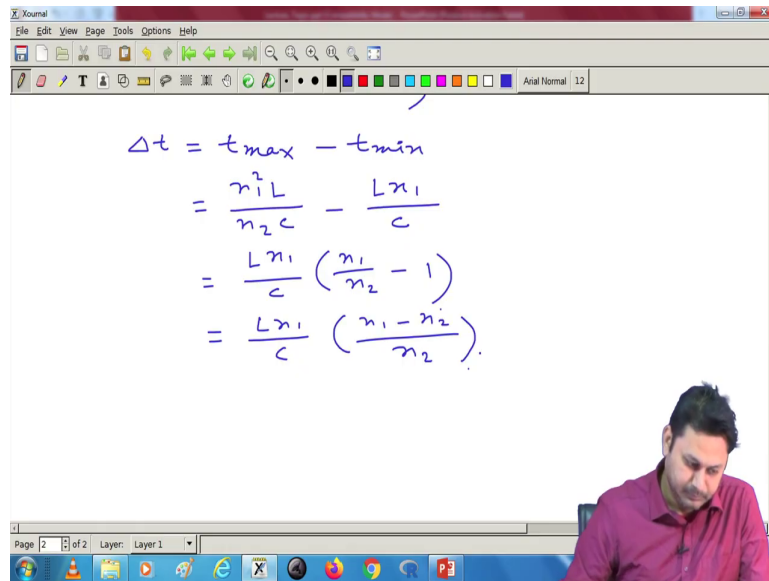

The screenshot shows a whiteboard with the following handwritten equations:

$$t_{\min} = \frac{n_1 L}{c}$$
$$t_{\max} = \frac{n_1^2 L}{c n_2}$$
$$\Delta t = t_{\max} - t_{\min}$$

The equations are grouped by a large curly brace on the right side. The software interface includes a menu bar (File, Edit, View, Page, Tools, Options, Help), a toolbar with various drawing tools, and a status bar at the bottom indicating 'Page 2 of 2' and 'Layer: Layer 1'.

So, let me write  $t_{\max}$  once again in terms of refractive indexes. I just want to remove this  $\sin \phi$ . So,  $n_1$  divided by  $L C \sin \phi$  is  $n_2$  and I have  $n_1^2$ . So, this is my  $t_{\max}$  and this is my  $t_{\min}$ , these two are final expression. So, what is the  $\Delta t$ ? So,  $\Delta t$  is the time lag between these two. So, I have  $t_{\max}$ , it should be  $t_{\max} - t_{\min}$ .

(Refer Slide Time: 19:05)

$$\begin{aligned}\Delta t &= t_{\max} - t_{\min} \\ &= \frac{n_1^2 L}{n_2 c} - \frac{L n_1}{c} \\ &= \frac{L n_1}{c} \left( \frac{n_1}{n_2} - 1 \right) \\ &= \frac{L n_1}{c} \left( \frac{n_1 - n_2}{n_2} \right)\end{aligned}$$

I have  $t_{\max}$  as  $n_1^2 L$  divided by  $n_2 C$  minus  $L n_1$  divided by  $c$ . So, I can have  $L n_1$  divided by  $C$  common, and then I can have something like  $n_1$  divided by  $n_2$  minus of 1, or  $L n_1$  divided by  $C$  is equal to  $n_1$  minus  $n_2$  divided by  $n_2$ .

(Refer Slide Time: 20:09)

Handwritten derivations on a presentation slide:

$$\Delta = \frac{n_1^2 - n_2^2}{2n_1^2} = \frac{NA^2}{2n_1^2}$$

For fibers  $n_1 \simeq n_2$

$$\Delta \simeq \frac{n_1 - n_2}{n_1}$$

$$\Delta t = \frac{L n_1}{c n_2} n_1 \Delta$$

$$= \frac{L n_1}{c n_2} n_1$$

Approximation for  $\Delta$ :

$$\Delta = \frac{n_1^2 - n_2^2}{2n_1^2} = \frac{(n_1 + n_2)(n_1 - n_2)}{2n_1^2}$$

$$n_1 + n_2 \simeq 2n_1$$

Now, I introduce a new parameter called delta which I write as  $n_1^2$  minus  $n_2^2$  whole divided by 2 of  $n_1^2$ . This is the definition. And if I look carefully  $n_1^2$  minus  $n_2^2$  is nothing but my NA square. So, NA square divided by 2  $n_1^2$ . Now, normally what happened for fibers?  $n_1$  is very nearly equal to  $n_2$ .

The refractive index difference is normally small. In that case, delta can be near delta can be written in terms of nearly equal to  $n_1$  minus  $n_2$  divided by  $n_1$ . Why it is that? Because originally delta is  $n_1^2$  minus  $n_2^2$  whole divided by 2  $n_1^2$  which is  $n_1$  plus  $n_2$ , and  $n_1$  minus  $n_2$  divided by 2 of  $n_1$ .

This  $n_1$  plus  $n_2$ , this  $n_1$  plus  $n_2$ , I can approximate as here is a square as 2 of  $n_1$ . So, if I make an approximation that since  $n_1$  is very close to  $n_2$ , so  $n_1$  plus  $n_2$  is very nearly equal

to  $2n_1$ , then  $\Delta t$  can be simplified as  $n_1$  minus  $n_2$  divided by  $n_1$ , which is just to write this stuff in this way.

(Refer Slide Time: 22:41)

The image shows a screenshot of a software window titled "Xournal" with a menu bar (File, Edit, View, Page, Tools, Options, Help) and a toolbar. The main workspace contains handwritten mathematical derivations in blue ink. On the left, the derivation for  $\Delta t$  is shown:  $\Delta t = \frac{L n_1}{c n_2} n_1 \Delta$  (boxed and checked), followed by  $= \frac{L n_1}{c n_2} n_1 \frac{NA^2}{2 n_1^2}$ , and finally  $\Delta t = \frac{L}{c n_2} \frac{NA^2}{2}$  (boxed and checked). On the right, the derivation for  $\Delta$  is shown:  $\Delta = \frac{NA^2}{2 n_1^2}$ , followed by  $\Delta = \frac{n_1^2 - n_2^2}{2 n_1^2}$ , then  $= \frac{n_1 - n_2}{n_1}$ , and finally  $NA = (n_1^2 - n_2^2)^{1/2}$ . A small note at the top right says  $n_1 + n_2 \approx 2 n_1$ . The bottom of the window shows a taskbar with various application icons and a system clock indicating 4:56 PM on 11/26/2020.

Then my  $\Delta t$  will be simply  $L n_1$ , I can write it as  $L n_1 c$  divided by  $n_2$  then  $n_1 \Delta$ . So, this is my original value of  $\Delta t$ . I just put  $n_2$  outside and put an  $n_1$  here. So, that  $\Delta$  is coming and I multiplied  $n_1$ , so that I can have this value. And also in terms of numerical aperture, if I look carefully in terms of numerical aperture, my  $\Delta$  is.

So this I can also write as  $\Delta$  was originally in terms of numerical aperture in this. So, we can write  $L n_1$  divided by  $C n_2$  then  $n_1 \Delta$  was originally  $NA^2$  divided by  $2 n_1^2$ . So, I can make use of that; so, I can make use of that and I can write it as  $\Delta$  let me write it  $\Delta$  equal to  $NA^2$  divided by  $2 n_1^2$ .

So, I will put it here.  $NA^2$  divided by 2 of  $n_1^2$  square. So, it becomes simply LC into  $NA^2$  divided by 2, this is also a way to write this. So, either I can write in this way or I can also write in this way in terms of delta. In many cases, the value of delta is given to a fiber.

If the value of delta is given to a fiber, then which should be the value of the dispersion, and this should be the value of the dispersion if the NA is given to the fiber. Let me erase this now; erase this part it looks ugly, yeah. So, and also you can see the definition of the delta and  $n_1 NA$  is slightly different.

So, delta I defined as  $n_1^2$  square minus  $n_2^2$  square divided by 2 of  $n_1^2$  square which is nearly equal to  $n_1$  minus  $n_2$  divided by  $n_1$ . On the other hand, NA is  $n_1^2$  square minus  $n_2^2$  square whole to the power half. If NA is given, then this delta  $t$  is my amount of dispersion. And if delta is given, then this is the amount of dispersion.

(Refer Slide Time: 26:22)

$$= \frac{L}{c n_2} n_1 \frac{NA^2}{2 n_1^2}$$

$$\boxed{\Delta t = \frac{L}{c n_2} \frac{NA^2}{2}} \checkmark$$

$$\left\{ \begin{array}{l} \Delta = \frac{n_1^2 - n_2^2}{2 n_1^2} \\ = \frac{n_1 - n_2}{n_1} \\ NA = (n_1^2 - n_2^2)^{1/2} \end{array} \right.$$

If NA is high  
Then dispersion is also high.

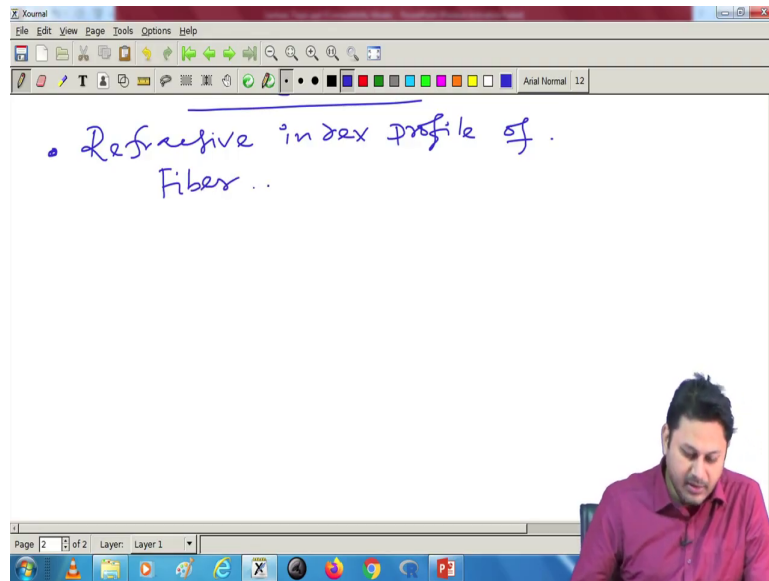

$\sin i_c \propto NA$  ✓

Now, you should note that there is a in delta t, we are having NA. So, if this is the important thing that if NA is high, then dispersion is also high.

If NA is high, the dispersion is also high. Previously, we have calculated that  $\sin i_c$  was proportional to NA that means, if I increase we want to increase the acceptance angle one can increase that by increasing NA. But here in this calculation we find that if I increase NA, the delta t has to be increased also, that means, delta t will going to increase if I increase NA.

So, if I want to have more and more light in the fiber, then I want to increase NA, so that  $i_c$  can be increased. But at the same point, in that kind of cases, my dispersion also be too high, so that is why it is not judicious to increase the NA because the dispersion will be high in this case.

(Refer Slide Time: 27:59)

Next we quickly discuss about the refractive index profile of fibers.

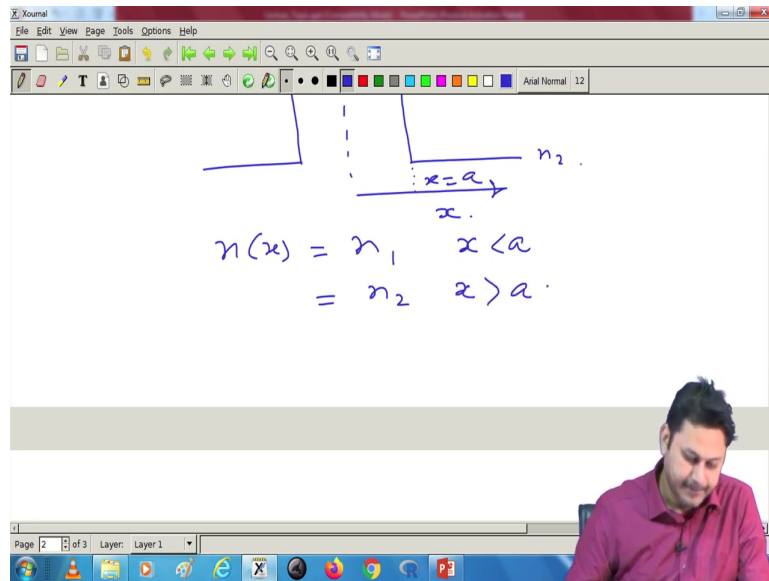

(Refer Slide Time: 28:38)

So, two kind of fiber refractive index profile I will going to mention today. And next class we will going to calculate something based on that. One is we already mentioned this one is step index fiber. For step index fiber, we simply have a step like structure like this. This is  $n_1$ ; this is  $n_2$ . And along this we have say  $x$ ; and this point is  $x$  equal to  $a$ .

(Refer Slide Time: 29:32)

So,  $n$ , which is a function of  $x$  can be written as  $n_1$  for  $x$  less than  $a$ , and equal to  $n_2$  for  $x$  greater than  $a$ .

(Refer Slide Time: 29:51)

Another kind of refractive index quickly I like to mention which is graded index. In graded index, the refractive index profile has a variation like this – a parabolic kind of variation. This is the central part. This is along  $x$ .

So, this  $n$  is a function of  $x$ . So, I have to be careful in defining  $n$ . In this case,  $n^2$  will be defined as  $n_1^2 \left[ 1 - 2\Delta \left( \frac{x}{a} \right)^2 \right]$  when  $|x| < a$ . This happens when  $|x| < a$ . And it should be  $n_2^2$  when  $|x| > a$ . This point is  $x = a$ .

(Refer Slide Time: 31:22)

$$\begin{aligned}
 n^2(x) &= n_1^2 \left[ 1 - 2\Delta \left( \frac{x}{a} \right)^2 \right] & |x| < a \\
 &= n_2^2 & |x| > a \\
 \Delta &= \frac{1}{2} \frac{(n_1^2 - n_2^2)}{n_1^2}
 \end{aligned}$$

At  $x = a$

$$\begin{aligned}
 n^2(a) &= n_1^2 \left[ 1 - 2\Delta \cdot (1) \right] \\
 &= n_1^2 - 2\Delta n_1^2 \\
 &= n_1^2 - n_1^2 + n_2^2 \\
 &= n_2^2
 \end{aligned}$$

Using the delta, I can also verify that what happened at x point. So, delta is equal to half of  $n_1^2$  minus  $n_2^2$  divided by  $n_1^2$  that we know. And if I put this delta here in the expression, then I can verify that at  $x$  equal to  $a$   $n^2(a)$  is simply becomes  $n_1^2$  minus  $2\Delta$  into  $n_1^2$  because I replace  $n_2^2$  by  $n_1^2 - 2\Delta n_1^2$  here.

So, this is simply  $n_1^2$  minus  $2\Delta n_1^2$ , and  $2\Delta n_1^2$  from here is  $n_1^2 - n_2^2$ . And  $2\Delta n_1^2$  here is  $n_1^2 - n_2^2$ ;  $n_1^2$  minus  $n_1^2$  plus  $n_2^2$ ;  $n_1^2$  minus  $n_1^2$  cancel out, so I will have this is  $n_2^2$ . So, at  $x$  equal to  $a$ , from the profile, we can see at this point, it is simply merges two value  $n_2^2$ . This is  $n_2^2$ . So, I plot it as  $n^2$ . So, if I plot I should write it y-axis as  $n^2$  as a function of  $x$ , so this value is square.

So, with this, I will like to conclude here. We do not have much time today. In the next class with these two profile, we are try to understand a general path equation, and how the ray will going to follow with this general path we calculate.

Thank you very much for your attention.
