Module 9: Fuel cell  
Lecture 37 : Introduction to Fuel Cells

Hello, so, let us start the first lecture of the next module. Today, I will be giving you an introduction to the field of fuel cells. Why do we need them? What are the advantages and disadvantages associated with fuel cells?

(Refer Slide Time: 00:45)

The slide has a blue header with the text 'CONCEPTS COVERED' in yellow. Below the header, a list of topics is shown: Hydrogen Fuel Cells, Alkaline Fuel Cells, and Types of Fuel Cells. The footer contains the IIT Kharagpur and NPTEL logos.

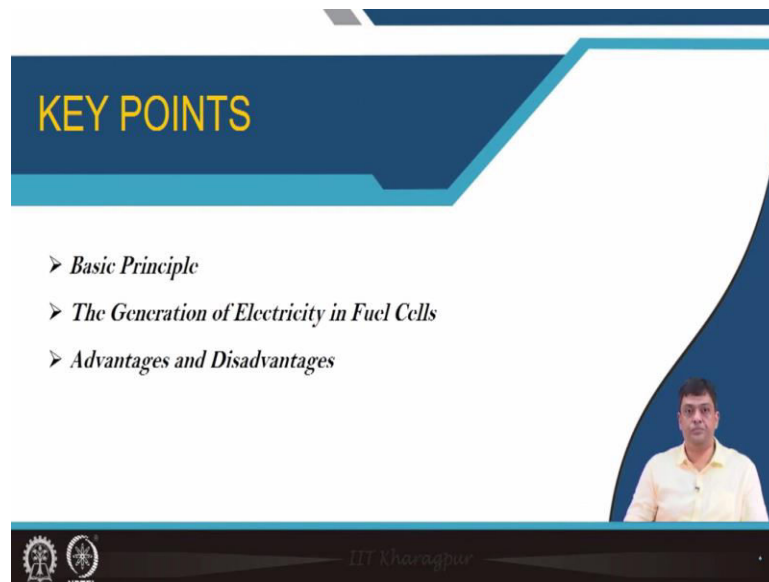

**CONCEPTS COVERED**

- Hydrogen Fuel Cells
- Alkaline Fuel Cells
- Types of Fuel Cells

IIT Kharagpur  
NPTEL

We will be focusing mostly on hydrogen fuel cells, alkaline fuel cells. And based on the discussion on these two types of fuel cells, we will also then go on to describe the other types of fuel cells which are there and are being investigated.

(Refer Slide Time: 01:07)

**KEY POINTS**

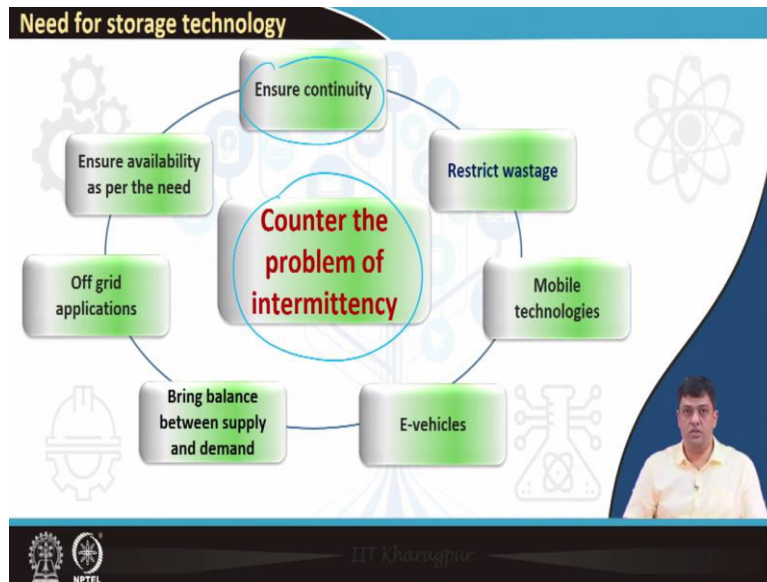

- *Basic Principle*
- *The Generation of Electricity in Fuel Cells*
- *Advantages and Disadvantages*

IIT Kharagpur

You will understand the basic principle which is used to fabricate or the principle which drives the fuel cell. Why this technology is once again coming back and generating interest as a source for electricity generation. Till now, there are been a lot of disadvantages associated with fuel cell technology that has led to reduced number of focused research going on in India for the last two decades or so.

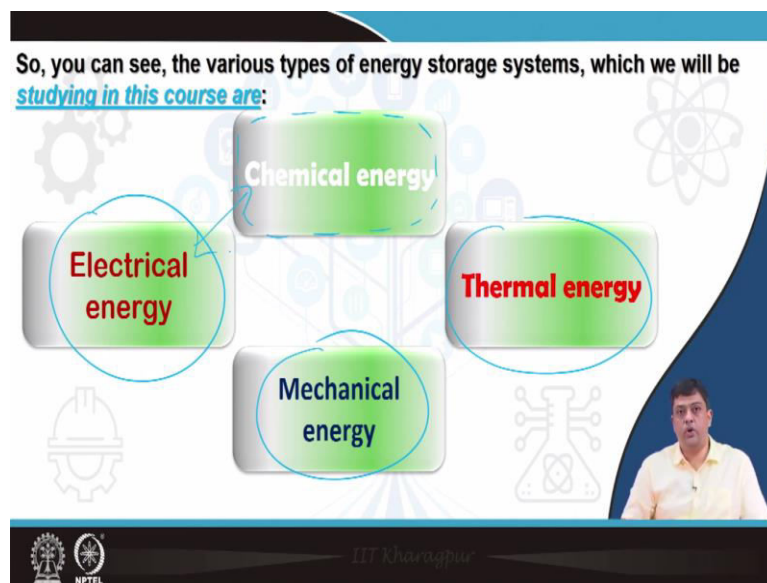

But now, with the advent of nanotechnology and nanomaterials and our understanding about these two concepts, that is nanotechnology and nanomaterials, we are once again reviving interest in the field of fuel cells. And you will understand why that is happening.

(Refer Slide Time: 02:07)

We started the discussion over the last three weeks or so, with the need for energy storage technology. We had mostly talked about three concepts that you need storage technologies to ensure continuity, to ensure sustainability and mostly to ensure that you are having the capability to counter the problem of intermittent nature of a renewable based source. And that was the reason why you had energy storage technologies.

(Refer Slide Time: 02:57)

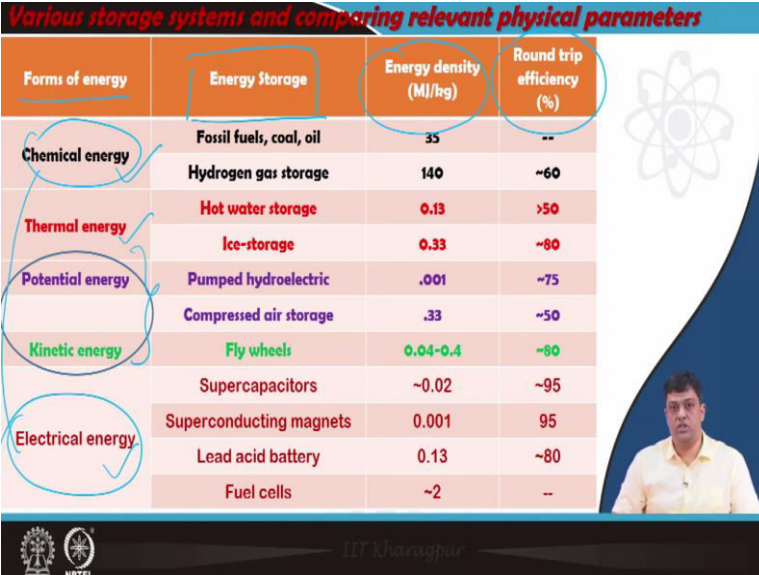

We have talked to you till now about thermal energy storage devices, we have talked to you about mechanical energy storage technologies, we have talked about electrical or electrochemical

energy storage technologies. And today, we will start with the final topic which is to be covered in this course, related to energy storage section, where we will talk about the fuel cell technology which is at the interface of electrical and chemical based energy storage technologies.

(Refer Slide Time: 03:45)

**Various storage systems and comparing relevant physical parameters**

Forms of energy	Energy Storage	Energy density (MJ/kg)	Round trip efficiency (%)
Chemical energy	Fossil fuels, coal, oil	35	--
	Hydrogen gas storage	140	~60
Thermal energy	Hot water storage	0.13	>50
	Ice-storage	0.33	~80
Potential energy	Pumped hydroelectric	.001	~75
	Compressed air storage	.33	~50
Kinetic energy	Fly wheels	0.04-0.4	~80
	Supercapacitors	~0.02	~95
Electrical energy	Superconducting magnets	0.001	95
	Lead acid battery	0.13	~80
	Fuel cells	~2	--

We had seen that depending upon the form of the energy that is either chemical, thermal, mechanical or electrical based, you can have very different energy densities or round tip efficiencies that are associated with the different kinds of energy storage devices that are put under a certain subheading. With this table, you see, we had mostly kept fuel cells under electrical energy. But there are people who also keep fuel cells at the interface of chemical and electrical energy.

So, this is a very good example, where we will use concepts like double layer formation at the electrode electrolyte interface that was leading to the storage capacity in capacitors or batteries. And then also, we will also talk about the use of catalysts in the systems which will lead to the change in the activation energy and the activation barriers, which are mostly used to explain various kinds of chemical reactions. So, therefore, the use of fuel cell can either be kept under chemical energy or electrical energy.

(Refer Slide Time: 05:36)

Till now, we have seen the energy storage technologies, where certain electrochemical reactions can be associated with the storage mechanism.

*Refer to: Lectures on batteries and supercapacitors.*

We have discussed include the potential energy, associated with the **chemical bonds of the molecules in fuel** such as wood or coal.

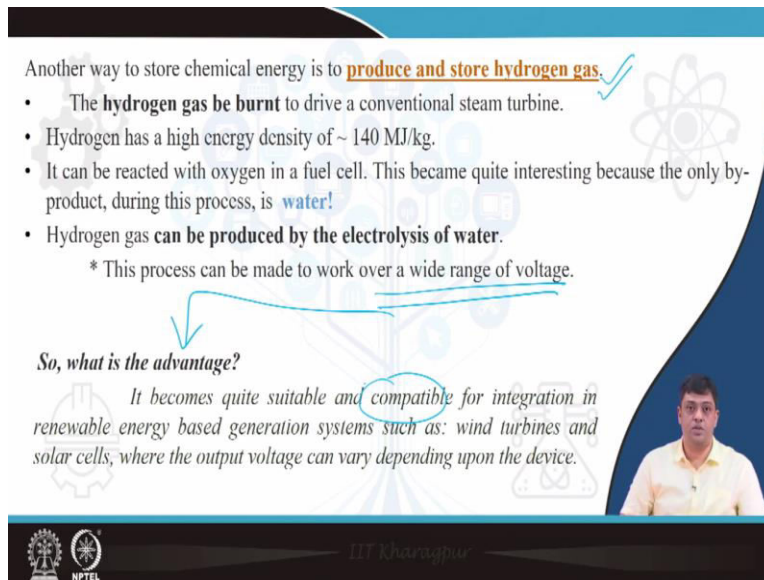

**In biological systems, the chemical bonds store solar energy.** This can be released by various processes such as: combustion, etc.

The slide features a presenter in a yellow shirt on the right side. The background is a blue gradient with a tree-like structure of icons representing various scientific and technological concepts. At the bottom, there are logos for IIT Kharagpur and NPTEL, along with the text 'IIT Kharagpur' and the number '7'.

Till now, we have seen a few energy storage technologies, predominantly the ones where we were using the electrochemical reactions and those were driving the storage mechanism. So, you can once again read and refer to the lectures or the notes on lithium-ion batteries and supercapacitors.

We have also discussed the use of potential energy associated with the chemical bonds of the molecules in fuels such as wood or coal that can lead to energy. We have also discussed biological systems where the chemical bonds store solar energy and then you can use these kind of systems to extract energy or drive processes such as combustion or other.

(Refer Slide Time: 06:50)

Another way to store chemical energy is to **produce and store hydrogen gas**.

- The **hydrogen gas be burnt** to drive a conventional steam turbine.
- Hydrogen has a high energy density of ~ 140 MJ/kg.
- It can be reacted with oxygen in a fuel cell. This became quite interesting because the only by-product, during this process, is **water!**
- Hydrogen gas **can be produced by the electrolysis of water**.
  - \* This process can be made to work over a wide range of voltage.

*So, what is the advantage?*

*It becomes quite suitable and compatible for integration in renewable energy based generation systems such as: wind turbines and solar cells, where the output voltage can vary depending upon the device.*

NPTEL IIT Kharagpur

Over the last few decades, we have now clearly realized that there is another way to store chemical energy and that is to produce and store hydrogen gas. If this hydrogen gas is burned, then it can be used to drive conventional steam turbine. So, you use hydrogen gas as the fuel and then the steam which is generated that can drive the turbines which we had discussed earlier. The advantage is that hydrogen has a very high energy density that is of the order of 140 mega joules per kg.

So, it is a huge energy density associated with the fuel and is much, much higher than your petroleum products. So, this can act as a fantastic source to drive steam turbines. In addition, if you play with the chemistry, then hydrogen can react with oxygen in a fuel cell or if you just consider reaction of hydrogen with oxygen, then it gives you a very interesting byproduct because the only by product which you get here is water.

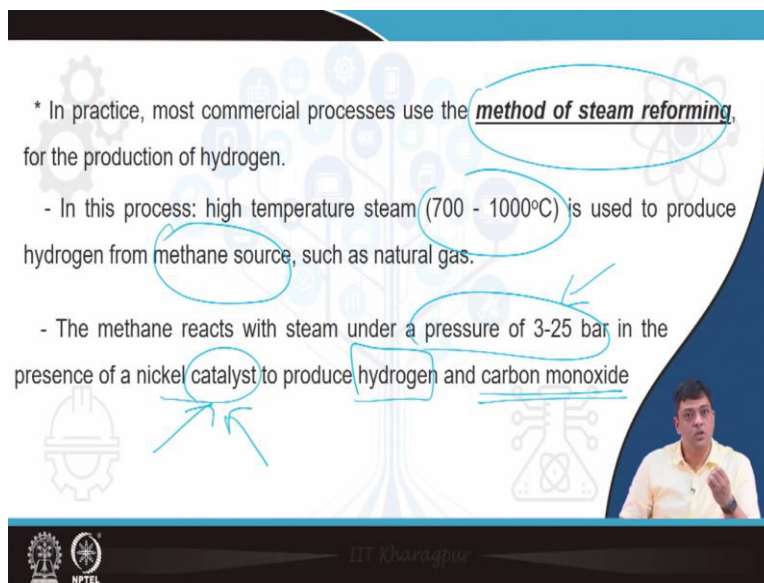

So, you can actually combine hydrogen and oxygen get water and during this reaction, if you can extract the heat, then you can also get heat energy or if you can get electrons then you can use it to drive an electrical circuit. Hydrogen gas can be easily produced by the electrolysis of water and this process can actually be made to work over a wide range of voltage.

So, you can electrolysis the water and what will happen you will get hydrogen. What is the immediate advantage you get? The immediate advantage becomes that this strategy becomes suitable and also compatible, it is important to understand suitability is there, but whether it is

compatible with the kind of energy generation units which we are learning, yes, it is also compatible, so that it can work together with the generation systems which we have discussed.

Generation systems like turbines, wind turbines, solar cells and because this process can work over a wide range of voltage, this gives an additional advantage that if you combine with wind turbines or solar cells, where the output can actually vary, then also the process will continue because it can work over a range of voltage. So, it becomes suitable and compatible for integration with the renewable based energy generation systems.

(Refer Slide Time: 10:23)

\* In practice, most commercial processes use the method of steam reforming, for the production of hydrogen.

- In this process: high temperature steam (700 - 1000°C) is used to produce hydrogen from methane source, such as natural gas.
- The methane reacts with steam under a pressure of 3-25 bar in the presence of a nickel catalyst to produce hydrogen and carbon monoxide

The slide features a background with faint icons of a gear, a lightbulb, and a chemical flask. A small inset video of a presenter is visible in the bottom right corner. The slide footer includes the IIT Kharagpur and NPTEL logos.

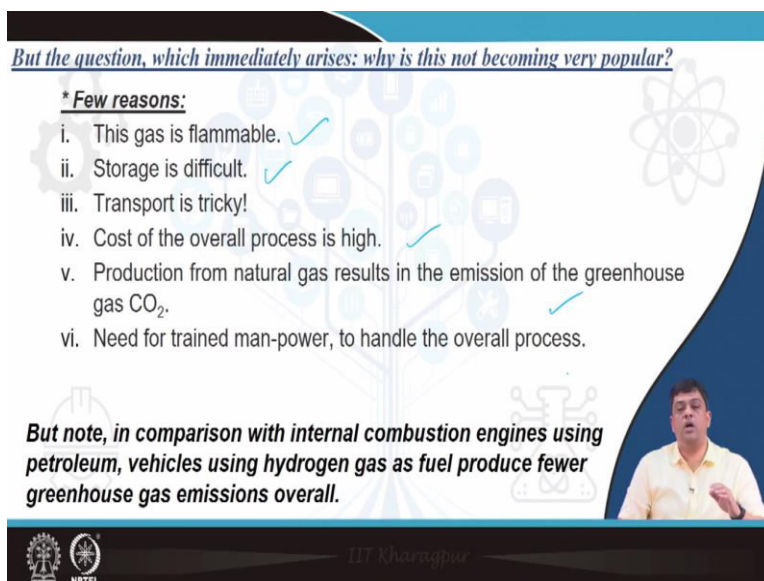

In practice, the most commercial process used to produce hydrogen is the method of steam reforming. This is the most common process where you have high temperature process and in this the high temperature steam is used to produce hydrogen from methane as the source and this can come from any natural gas also. What happens? Methane reacts with steam at slightly higher pressures in presence of a catalysts and this produces hydrogen and carbon monoxide.

You should understand that this reaction is actually taking place at high temperature as well as high pressure and it is using a catalyst. How do you actually perform this experiment? Increasing the temperature is understood, but at the same time you are talking about conditions where you should also ensure that the pressure is high.

You will see in the next module that there are various processes where you can initiate such kind of reactions, where pressure can also be increased and temperature can also be increased simultaneously and then the reaction can be induced. If some of you already know or have an idea about the protocols, then we are indicating towards the hydrothermal processes.

You have already seen that I have marked a point which is catalysts. Now, catalyst what is the role of catalyst in these kinds of reactions? We have not used catalyst till now in any other discussions earlier then why do we need catalyst? So, these concepts will also become clear as we go along.

(Refer Slide Time: 13:02)

*But the question, which immediately arises: why is this not becoming very popular?*

**\* Few reasons:**

- i. This gas is flammable. ✓
- ii. Storage is difficult. ✓
- iii. Transport is tricky!
- iv. Cost of the overall process is high. ✓
- v. Production from natural gas results in the emission of the greenhouse gas CO<sub>2</sub>. ✓
- vi. Need for trained man-power, to handle the overall process.

***But note, in comparison with internal combustion engines using petroleum, vehicles using hydrogen gas as fuel produce fewer greenhouse gas emissions overall.***

Dr. Khanna

NPTEL

So, it looks to be very advantageous, it looks to be simple, then why is it not becoming very popular or visible around us? There are reasons which are still to be addressed before this technology becomes readily available to common use. The reasoning which can be listed are the gas is flammable. So, that is known to us. Now, how do you actually store hydrogen you just cannot store in, in a vessel. So, how do you store hydrogen gas?

There are various strategies now being proposed and you will see that one of the most common strategy which is coming out is the use of hydrogen storage materials. Again, you will see that materials will play a very important role in storage of the gas itself. And there are various types of materials being proposed. Till now, transport is bit tricky, how do you transport this gas and because of these processes the cost increases.

But you see that you are actually, during the reaction you can lead to emission of greenhouse gases. And all the processes which we have discussed can only be tackled by trained manpower. And therefore, you need to have highly skilled and trained manpower which is not easy or is not cheap you if you have skills, if you are trained manpower, then the cost also goes up of the overall process because you are associating salary of these trained manpower's.

But the advantage remains that in comparison to the internal combustion engines which are using petroleum products, the vehicles or the engines or the processes using hydrogen gas as the fuel produce fewer greenhouse gases overall. So, the number of gases which are going to impact the environment comes down and therefore, the use of hydrogen as the fuel gives you an added advantage that you can actually reduce the overall carbon footprint.

(Refer Slide Time: 15:59)

(Refer Slide Time: 16:06)

**Hydrogen Fuel Cells: Basic Principles**

- 1) The first demonstration of a fuel cell was by lawyer, who was also an inventor: William Grove in 1839.
- 2) (a) Water is electrolyzed into hydrogen and oxygen, by passing an electric current through it.
- 3) (b), the power supply has been replaced with an ammeter, and a small current is flowing.

*The electrolysis is being reversed- the hydrogen and oxygen are recombining, and an electric current is being produced.*

Labels in diagram: Dilute acid electrolyte, Platinum electrodes, (a), (b). Note: Note that the arrows represent the flow of negative electrons from - to +.

NPTEL

So, let us see how these solutions have come up in fuel cell. In fact, as we have been discussing and moving in most of the modules so let us again proceed in the same manner in this module also. Let us see the development of fuel cell. The concept of fuel cell actually was proposed way back in 1839 by a lawyer, William Grove. And he was a lawyer by profession by but an inventor. So, he was inventing high end scientific or technological devices or scientific concepts were being proposed by William Grove.

And the first example of a fuel cell is actually attributed to William Grove which he had proposed in 1839. So, what you see in the figure a, is that water is, is electrolyzed into hydrogen and oxygen by passing an electrical current through it. And if you reverse the process, then you see in figure b, what is happening, you are having the power supply which is replaced by an ammeter and a small current is flowing through it, because you have reversed the process where hydrogen and oxygen are now recombining and a small electric current is being produced.

(Refer Slide Time: 17:59)

*Visualizing fuel cell: you can say that hydrogen fuel is being burnt or combusted in the simple reaction:*

$$2\text{H}_2 + \text{O}_2 \rightarrow 2\text{H}_2\text{O}$$

*However, instead of heat energy being liberated, electrical energy is produced.*

*The experiments described the functioning of a hydrogen fuel cell but the current produced were very small. The main reasons for this being:*

- The low 'contact area' between the gas, the electrolyte and the electrode.*
- The large distance between the electrodes and the electrolyte resists the flow of electric current.*

**SO HOW DO WE OVERCOME THIS?**

IT Khanna

NPTEL

So, if you visualize a fuel cell in a very simple manner, what are you having? You can say that you are using hydrogen fuel which is being burned in a simple reaction to get water. So, you have the reaction. But instead of the heat energy being liberated, you are getting the electrical energy. The experiments describe the functioning of the hydrogen fuel cell, but the currents which were obtained were very small.

And hence, the whole idea was accepted but it did not kick off rapidly. The limited current which you were observing at that time, if you see the literature, then the main reasons which now can be attributed to the observation of low current are that the low contact area between the gas, the electrolyte and the electrode. So, effectively the reaction was happening at a very small area. And therefore, the currents which you are obtaining were quite low.

In addition, there was a large distance between the electrodes. So, the electrodes were far apart and the electrolyte had the resistive effects and the electrolyte itself resisted the flow of electric current. So, if I tell you that these are the two limitations of the first fuel cell which was supposedly proposed, what will you say? Why do not you use an electrode which has large area?

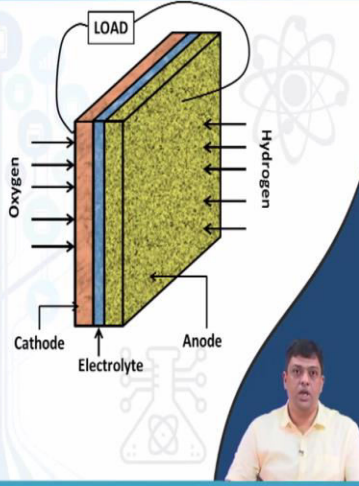

In addition, you ensure that the contact between the electrolyte the gas and the electrode actually occurs over a large area, it is not just that you increase the area of the electrode, but do not ensure that the design is such that the, the interaction between the three is again in a limited area. So,

you must ensure that the interaction between the gas, the electrolyte in the electrode is also over a large surface area. So, what will you do?

(Refer Slide Time: 20:31)

**Overcoming the problem of low current**

- ❖ The electrodes are usually made flat with a thin layer of electrolyte.
- ❖ The structure of the electrode is porous, so that both the electrolyte from one side and the gas from the other can penetrate it.
- ❖ This is to give the maximum possible contact between the electrode, the electrolyte and the gas.

The diagram illustrates a fuel cell cross-section. On the left, the Cathode is shown with Oxygen entering. On the right, the Anode is shown with Hydrogen entering. A thin layer of Electrolyte is positioned between the two electrodes. A LOAD is connected across the electrodes. The porous structure of the electrodes allows both gas and electrolyte to penetrate, maximizing contact area.

IT Khanna

And that was actually addressed in a very simple manner. So, what was done? The electrodes were then made flat with a thin layer of electrolyte. So, you had larger size electrodes, but they were flat. So, electrolyte were interacting throughout the surface of the electrode. In addition, you also have to introduce the gas. Gas if it is coming from the ambient surrounding. Then what you need to do? Then, you need to allow the gas to go in. Going from where? From the electrode.

Now, if the gas has to move in, then the idea was that the structure of the electrodes were so, that it was porous in nature. So, it was allowing the gas to penetrate and then you had the interaction of the electrolyte, the gas and you had the electrode which was facilitating the interaction. This way you had higher contact between the electrode, the electrolyte and the gas and the currents which you obtain could be enhanced.

(Refer Slide Time: 21:59)

**Understanding the generation of electricity in Acid Electrolyte Fuel Cells**

- ❖ At the anode of an acid electrolyte fuel cell, the hydrogen gas ionizes, releasing electrons and creating H<sup>+</sup> ions (or protons):  
$$2\text{H}_2 \rightarrow 4\text{H}^+ + 4\text{e}^-$$
- ❖ **This reaction releases energy.**
- ❖ At the cathode, oxygen reacts with electrons take from the electrode, and H<sup>+</sup> ions from the electrolyte, to form water.  
$$\text{O}_2 + 4\text{e}^- + 4\text{H}^+ \rightarrow 2\text{H}_2\text{O}$$

Hydrogen fuel

Anode

$2\text{H}_2 \rightarrow 4\text{H}^+ + 4\text{e}^-$

H<sup>+</sup> ions through electrolyte

Cathode

$\text{O}_2 + 4\text{e}^- + 4\text{H}^+ \rightarrow 2\text{H}_2\text{O}$

Electrons flow round the external circuit

Oxygen, usually from the air

LOAD  
e.g. electric motor

NPTEL

Dr. Khanna

So, if you want to see the reactions, what was basically happening? So, you had the anode, the cathode. Electrons flow around the external circuit, oxygen is usually from the air and you were using hydrogen as the fuel. So, you had hydrogen breaking into 4H plus and giving 4 electrons. Now, H plus half ions have to go through. But do you actually want that the electrons should also go through? If you allow the electrons to go through, what will happen?

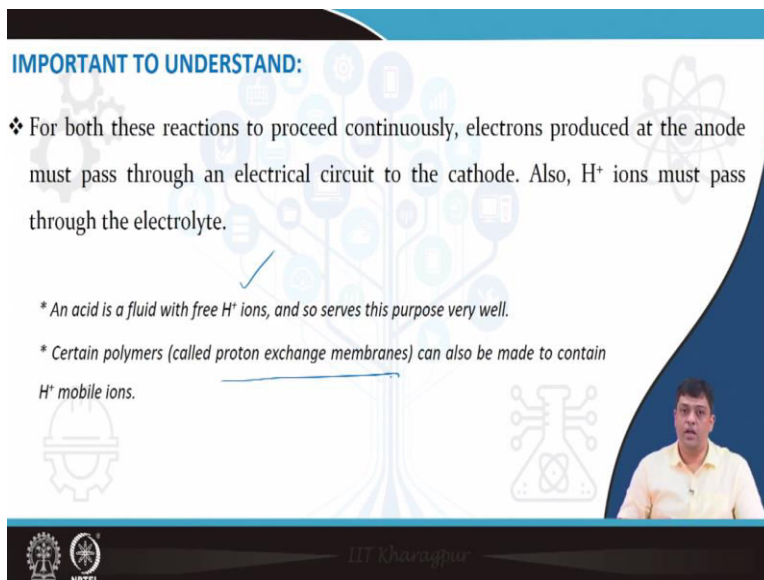

You will have short circuit. So, do you want that obviously not, but you want you want H plus to go through so, that the electrons can go through the external circuit and then recombine in the cathode side and you have the charge neutrality condition and what you get is water. So, what should be the nature of the electrolyte? It should be proton conducting. So, it should be proton conducting, but not electron conducting.

Again, just like the concept we are, we had discussed in batteries and capacitor you should have ion conducting membrane, but not the ion conducting membrane which was being used as the separator in those two technologies, which we discussed in the previous three weeks. So, you now, you have the anode, the cathode and the electrolyte. I have repeated these three things anode, cathode and electrolyte.

You have already seen in the previous modules that you can have different types of anodes; you can have different types of cathodes and you can also have different kinds of proton conducting electrolytes or membranes. And hence, you can now easily make different kinds of fuel cells,

because you can synthesize different kinds of cathodic material or anodic materials and also you can have different kinds of electrolytes or membranes. Hence, the fuel cell technology is coming back and attaining prominence.

(Refer Slide Time: 24:50)

**IMPORTANT TO UNDERSTAND:**

- ❖ For both these reactions to proceed continuously, electrons produced at the anode must pass through an electrical circuit to the cathode. Also,  $H^+$  ions must pass through the electrolyte.

*\* An acid is a fluid with free  $H^+$  ions, and so serves this purpose very well.*

*\* Certain polymers (called proton exchange membranes) can also be made to contain  $H^+$  mobile ions.*

The slide features a background with faint icons of a gear, a lightbulb, a tree, and a molecular structure. A small video inset of a man in a yellow shirt is visible in the bottom right corner. The footer includes the IIT Kharagpur and NPTEL logos.

At this point, please remember I have mentioned two things that electrons produced at the anode must pass through the electrical circuit so as to reach the cathode and the protons must pass through the electrolyte. And I hope you remember what is an acid? Acid is something which has free  $H^+$  ions and hence, this can work as a very good electrolyte in acid fuel cell and you can also otherwise replace this with proton action membranes, which actually does the same purpose that they allow the protons to go through whereas, they prevent the flow of electrons.

(Refer Slide Time: 25:49)

### Alkaline electrolyte fuel cell

- ❖ The overall reaction is the same but the reactions at each electrode are different.
- ❖ In an alkali hydroxyl (OH<sup>-</sup>) ions are available and mobile.
- ❖ At the anode these react with hydrogen, releasing energy and electrons, and producing water.  
$$2\text{H}_2 + 4\text{OH}^- \rightarrow 4\text{H}_2\text{O} + 4e^-$$

The diagram illustrates the internal structure of an alkaline electrolyte fuel cell. It shows a cross-section with an Anode on top and a Cathode on the bottom, separated by an electrolyte. Hydrogen fuel is supplied to the anode, and oxygen, usually from the air, is supplied to the cathode. The anode reaction is  $2\text{H}_2 + 4\text{OH}^- \rightarrow 4\text{H}_2\text{O} + 4e^-$ . The cathode reaction is  $\text{O}_2 + 4e^- + 2\text{H}_2\text{O} \rightarrow 4\text{OH}^-$ . OH<sup>-</sup> ions flow through the electrolyte from the cathode to the anode. Electrons flow from the anode to the cathode through an external circuit, which is connected to a load (e.g., electric motor). The overall reaction is  $2\text{H}_2 + \text{O}_2 \rightarrow 2\text{H}_2\text{O}$ .

Hydrogen fuel

Anode

$2\text{H}_2 + 4\text{OH}^- \rightarrow 4\text{H}_2\text{O} + 4e^-$

OH<sup>-</sup> ions through electrolyte

Cathode

$\text{O}_2 + 4e^- + 2\text{H}_2\text{O} \rightarrow 4\text{OH}^-$

Oxygen, usually from the air

Electrons flow round the external circuit

LOAD

e.g. electric motor

DT Kharagpur

The next one came was that you replaced your acidic electrolytes and then you started using alkaline electrolytes and you had the advent of alkaline electrolyte fuel cells or AFC's, Alkaline Fuel Cells. The overall reaction is the same, but the reactions at each electrodes are slightly different. So, the overall functioning is the same, but what you get is slightly different. So, now, you are getting 4OH minus radicals.

So, you are getting alkaline hydroxyl ions and these are mobiles and at the anodes these react with hydrogen releasing energy and electrons and producing water. So, the concept was similar, but now, the flow of the mobile ion which you are considering is slightly different. So, there you are considering the flow of H plus and now you are considering the flow of OH minus. And then therefore, the reactions which are taking place occur at the different electrodes and the byproduct which you see is now at the anode.

(Refer Slide Time: 27:18)

### Connecting cells in series - The Bipolar Plate

Oxygen fed to each cathode

Hydrogen fed to each anode

Cathode

Anode

Electrolyte

Load

For reaction in this part, the electrons have to pass all along the face of the electrode

IIT Kharagpur

NPTEL

(Refer Slide Time: 27:35)

### 2.0. Alkaline electrolyte fuel cell

- ❖ At the cathode, oxygen reacts with electrons (taken from electrode), and water in the electrolyte, forming new  $\text{OH}^-$  ions.  
$$\text{O}_2 + 4\text{e}^- + 2\text{H}_2\text{O} \rightarrow 4\text{OH}^-$$
- ❖ For reaction to continue, there must be an electrical circuit for the electrons to go from the anode to the cathode.
- ❖ In comparison to acid FC, twice as much hydrogen is needed as oxygen. Also note that, although water is consumed at the cathode, it is created twice as fast at the anode.

IIT Kharagpur

NPTEL

You can combine these cells together and you can again get the stack of fuel cells and then you can increase the overall current which can flow through the external point. So, at this point, we have already seen the reactions which take place in the alkaline electrolyte fuel cell and in comparison, to the acidic fuel cell twice as much hydrogen is needed as oxygen but, water is consumed in cathode it is created twice as fast as the anode. So, you do consume water, but you also produce water at a much faster rate.

(Refer Slide Time: 28:14)

**Construction of a fuel cell**

- Anode** A layer of material which acts as anodic catalyst. Material with high electronic conductivity and zero proton conductivity.
- Electrolyte** A material that is sandwiched between anode and cathode and have high protonic conductivity and zero electron conductivity.
- Cathode** A layer of material which acts as cathodic catalyst. Material with high electronic conductivity and zero proton conductivity.
- Catalyst** A material that helps to speed up the reaction within a fuel cell. Mostly platinum is used as the catalyst.

The slide features a blue header with the title 'Construction of a fuel cell'. Below the title, four components are listed in colored boxes: Anode (orange), Electrolyte (yellow), Cathode (blue), and Catalyst (green). Each component is accompanied by a descriptive text. The background of the slide is dark blue with faint icons of a gear, a lightbulb, and a molecular structure. A small inset video of a man in a yellow shirt is visible in the bottom right corner. At the bottom, there are logos for IIT Kharagpur and NPTEL.

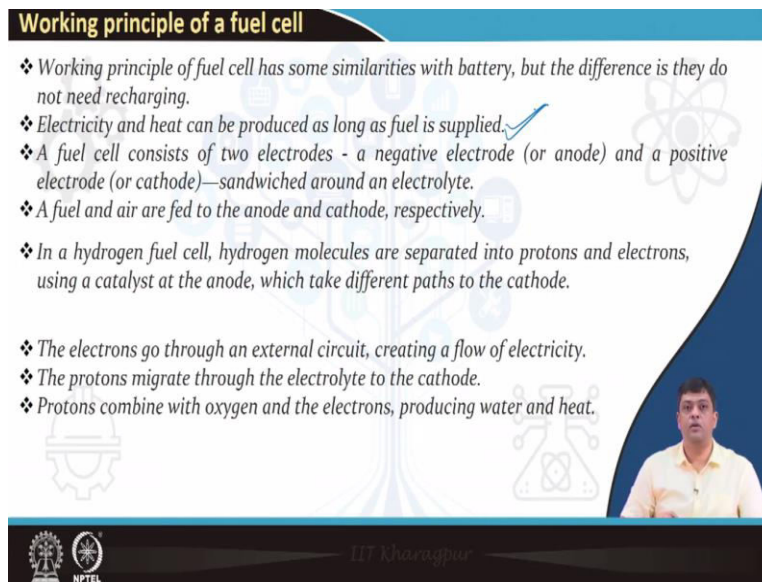

Now, one thing must be clear to you, the functioning of fuel cell will depend on what it will depend on the kind of anode material you use, the electrolyte you use, the cathode material which you use and in addition, a new concept comes into picture that is catalyst. Because, if you can increase the rate of reaction, then the overall process will become even more efficient.

And catalysts are therefore, used in fuel cells so, as to speed up the reactions within the fuel cells. And mostly till date, platinum is used but with the advent of nanotechnology and nanomaterials, there are much cheaper, readily available and useful catalysts which can be produced in bulk are being utilized to develop the next generation fuel cells.

(Refer Slide Time: 29:33)

**Working principle of a fuel cell**

- ❖ Working principle of fuel cell has some similarities with battery, but the difference is they do not need recharging.
- ❖ Electricity and heat can be produced as long as fuel is supplied.
- ❖ A fuel cell consists of two electrodes - a negative electrode (or anode) and a positive electrode (or cathode)—sandwiched around an electrolyte.
- ❖ A fuel and air are fed to the anode and cathode, respectively.
- ❖ In a hydrogen fuel cell, hydrogen molecules are separated into protons and electrons, using a catalyst at the anode, which take different paths to the cathode.
- ❖ The electrons go through an external circuit, creating a flow of electricity.
- ❖ The protons migrate through the electrolyte to the cathode.
- ❖ Protons combine with oxygen and the electrons, producing water and heat.

So, I hope the working of the fuel cell is clear by now and this is just the revision of the same, if you want to understand everything I have said till now. There is a slight difference between the working principle of a fuel cell from the battery. What is that? That fuel cells do not need recharging.

And you have already seen that during the working of a fuel cell electricity and heat can be produced as long as the fuel is supplied. So, you keep on supplying hydrogen and the process will continue. The main components are the anode, the cathode material, the electrolyte and in addition the catalysts.

(Refer Slide Time: 30:35)

**Advantages of Fuel cell**

- ✓ **Water is the only product that comes out of the cell**
- ✓ **Excellent load characteristic**
- ✓ **Zero emission**
- ✓ **Appreciable high efficiency than conventional engines**
- ✓ **Long cycle life**
- ✓ **No noise pollution**

IIT Kharagpur  
NPTEL

So, the immediate advantages which you can see that water is the byproduct which you are obtaining. It can have excellent load characteristics. If you have water as the byproduct then the overall emission which you are talking is practically zero which is emission in terms the ones which are going to affect the environment. So, you do not have toxic emissions.

The process can be quite efficient if you use efficient materials. As you have seen, that the process can continue as long as the fuel is being supplied. So, you have long cycle life of these fuel cells and the operation is quite silent. And so, the overall functioning of the fuel cell does not lead to noise pollution.

(Refer Slide Time: 31:36)

**Disadvantages of Fuel cell**

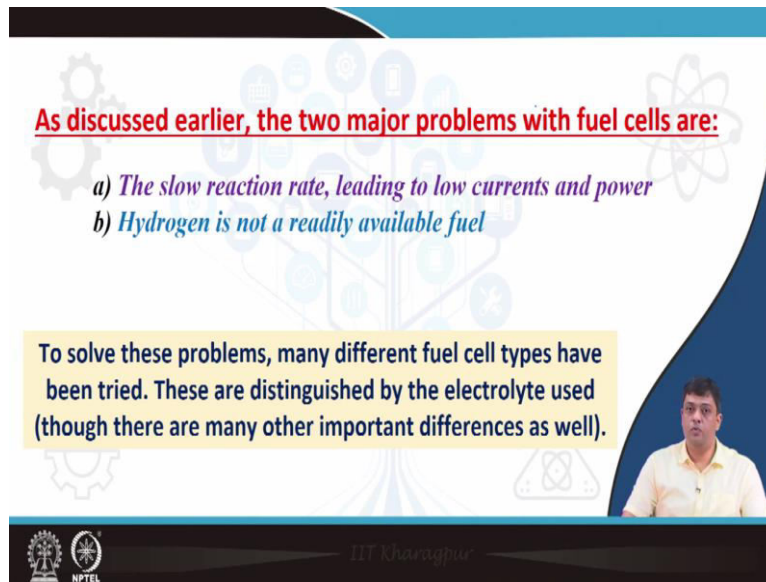

- **Efficient but lot more needs to be delivered!**
- **Handling  $H_2$  is very difficult**
- **Expensive i.e. cost of implementation is high**
- **Sometimes the discharge of  $CO_2$  is a problem**

The slide features a background with various icons including gears, a tree, a hard hat, and a chemical flask. A presenter is visible in the bottom right corner. The footer includes the IIT Kharagpur and NPTEL logos.

But there are still disadvantages which are associated with the operation or the construction of the fuel cells. And once you can overcome this, the disadvantages mentioned here, fuel cells will become quite important to us. They are efficient, but lot more needs to be delivered in terms of energy densities coming out of these fuel cells.

Till you have even more efficient materials to store hydrogen and then deliver it for ensuring the working of the fuel cells, handling of hydrogen continues to be a limiting factor. Overall construction is still on the expensive side because you use expensive catalysts, the fabrication of the membranes and the, the whole system involves many steps. And therefore, the product, the product becomes quite expensive. And sometimes the discharge of  $CO_2$  is a big problem.

(Refer Slide Time: 32:56)

**As discussed earlier, the two major problems with fuel cells are:**

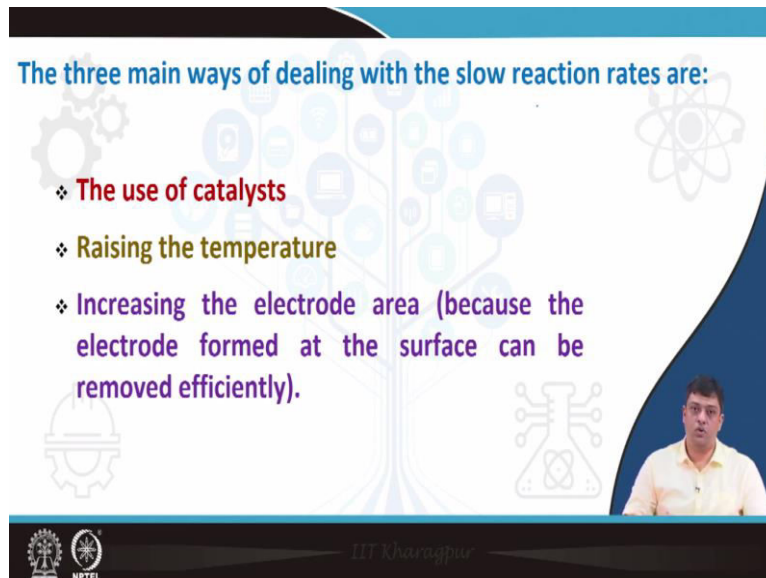

- a) *The slow reaction rate, leading to low currents and power*
- b) *Hydrogen is not a readily available fuel*

To solve these problems, many different fuel cell types have been tried. These are distinguished by the electrolyte used (though there are many other important differences as well).

IIT Kharagpur

So, just a revision. What are the two major problems? Slow reaction rate, leading to low currents and powers. And hydrogen is still not readily available fuel and there are problems associated with the transport of hydrogen itself. So, if you can counter these problems, you will get the advantages which are quite a few and then fuel cells will become very useful to us.

(Refer Slide Time: 33:38)

**The three main ways of dealing with the slow reaction rates are:**

- ♦ **The use of catalysts**
- ♦ **Raising the temperature**
- ♦ **Increasing the electrode area (because the electrode formed at the surface can be removed efficiently).**

IIT Kharagpur

So, what are the ways people are working and you can see that these are the factors which can be used to counter these low reaction rates. If you want to increase the reaction rate, what should be the way? Obviously, people will say yes use a catalyst or you raise the temperature so that the

activation barrier height lowers down and then the transfer can take place and you have the reactions moving much faster.

And in addition, increase the electrode area so that the contact between the gas, the electrolyte and the electrode, where you have deposited the catalysts also that can increase and then you have a higher reaction rates. So how do you want to increase the electrode area? Maybe from previous modules also you have seen that probably we are indicating towards the use of nanomaterials where you will have very high specific surface areas and that can lead to enhanced contact areas between the gas, the electrolyte and the electrodes area.

So, based on the operation, based on the kind of membranes or the temperature range or the source of fuel which you are using there are various types of fuel cells, you have alkaline fuel cells, you have phosphoric acid fuel cells, you have molten carbonate fuel cells, you have solid oxide fuel cells, then you have polymer electrode to membrane fuel cell and a technology which is very interesting, where you use the bio wastes as the source for extracting electrons is the microbial fuel cells and a lot of work is actually being done in India in this field.

(Refer Slide Time: 36:01)

Fuel cell type	Mobile ion	Operating Temp. (°C)	Applications
Alkaline (AFC)	OH <sup>-</sup>	50-200	Space vehicles
Proton exchange membrane (PEM)	H <sup>+</sup>	50-100	Vehicles and mobile applications
Phosphoric acid	H <sup>+</sup>	~ 220	200kW CHP systems
Molten carbonate	CO <sub>3</sub> <sup>2-</sup>	~ 650	Medium to large scale CHP systems, upto MW capacity.
Solid Oxide	O <sup>2-</sup>	500-1000	All sizes of CHP systems, 2kW to multi MW
Direct Methanol fuel cell (DMFC)		120-190	Military and electronic equipment
Zinc air fuel cell	O <sup>2-</sup>	50-200	High specific energy applications
Microbial Fuel Cells	Micro-organism	20-50	Medical devices, water treatment, breweries

In terms of their operating temperatures, you can clearly see that it can vary. So, you can use different kinds of fuel cells, they will be operated in different temperature range, you will have different kind of mobile ions in these fuel cells and they will be using different kind of catalysts and based on the energy densities which you can get out of these fuel cells, the range of applications can be quite varied. So, you can go from water treatment to space vehicles and they are all dependent on the parameter that is energy densities delivered by the fuel cells.

**What limits the current?**

- ❖ At the anode hydrogen reacts, releasing energy.
- ❖ However, just because energy is released, this does not mean that the reaction proceeds at an unlimited rate.
- ❖ The reaction has a classical form shown in the Figure.
- ❖ If the probability of a molecule having enough energy to cross the activation (energy) hill, is low then the reaction moves very slowly.

The diagram shows a graph of Energy versus Stage of reaction. The y-axis is labeled 'Energy' and the x-axis is labeled 'Stage of reaction'. The curve starts at a horizontal line, rises to a peak, and then falls to a lower horizontal line. A vertical double-headed arrow between the starting and ending levels is labeled 'Energy released'. A vertical double-headed arrow between the starting level and the peak is labeled 'Activation energy'.

In the next lecture onwards, you will see that the limiting factors again come from the activation barrier. And how do we counter this limitation will become clear in the next two lectures. I have just given you this slide so, that you have an idea as to what is the problem which is there and how are we countering this problem in the fuel cell technology.

**CONCLUSION**

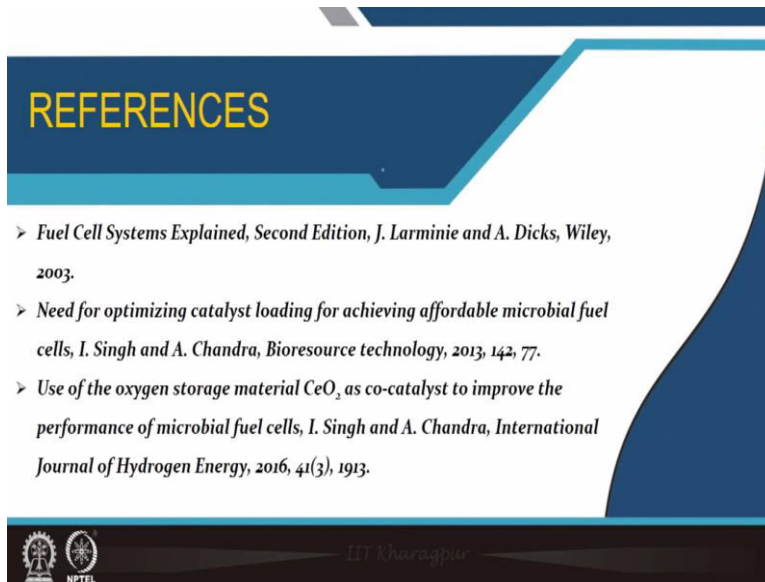

- *Introduction to fuel cells was given in the lecture.*
- *There are various types of fuel cells, which are being investigated. These were also presented.*
- *The advantages and disadvantages, associated with fuel cell technology was also discussed.*

NPTEL  
IIT Kharagpur

So, I hope today you have understood the basics of fuel cell. What are the various types of fuel cells? Why do we classify the fuel cell based on the materials that are used to fabricate the fuel cells? What are the reactions taking place in fuel cells, the advantage that you have zero emission of toxic waste and mostly you have water as the byproduct which is a big advantage in the fuel cell technology?

But there are also disadvantages associated with this technology that needs to be addressed before fuel cells become very important to us. These are the major references which were used to prepare the lecture notes today, and you can refer to them for further knowledge and I thank you for attending today's lecture.
