Quantization of Electromagnetic Field II

(Refer Slide Time: 00:18)

So, we are discussing the covariant quantization, the Lagrangian density is given by $\mathcal{L} = -\frac{1}{4} F_{\mu\nu} F^{\mu\nu} - \frac{\lambda}{2} (\partial_\mu A^\mu)^2$. We have modified this Lagrangian density by $A_\mu \partial^\mu A^\mu$, which is proportional to $\partial_\mu A^\mu$. This is the Lagrangian density we will consider and then we will quantize this. Of course, this is not as the same as the Maxwell say Lagrangian density, but because of the presence of this additional term, but we will make sure that the additional term does not have any physical effect adding this additional term does not have any physical effect.

So let us so the Feynman gets in this notation correspond to $\lambda = 1$. Although, you can consider this for any general λ its we will fix a λ to be a specific value. We will do quantize you can consider λ to be any arbitrary number. Then you can quantize it nothing will change. So, yes I could include yesterdays notation it will be $\lambda = \frac{1}{2}$, which is the gauge will we will be working the equation of motion is a given by $\partial_\alpha A_\beta - \partial_\beta A_\alpha = 0$.

So, let us compute this quantity $\partial_\mu \partial^\mu A^\alpha$ this one will give me $A^\alpha - \eta^{\alpha\beta} \partial_\beta \partial^\mu A_\mu$. Now, you know why I chosen this vector two here, because I want to do this to cancel, here that is the reason I am choosing to.

So, the equation of motion is just $\partial_\mu \partial^\mu A^\alpha - \lambda \partial^\alpha \partial_\mu A^\mu = 0$. So, let us work out what we get $\partial_\mu \partial^\mu A^\alpha - \partial^\alpha \partial_\mu A^\mu + \lambda \partial^\alpha \partial_\mu A^\mu = 0$. This one is nothing but $\partial_\mu \partial^\mu A^\alpha - \partial^\alpha \partial_\mu A^\mu + \lambda \partial^\alpha \partial_\mu A^\mu = 0$. Because, μ is a dummy index here I can change it to α .

Then what I see is the equation of motion is basically $\partial_\mu \partial^\mu A^\alpha - \partial^\alpha \partial_\mu A^\mu + \lambda \partial^\alpha \partial_\mu A^\mu = 0$. This is the equation of motion you can see that. This equation here implies $\partial_\mu \partial^\mu A^\alpha = 0$. So, $\partial_\mu \partial^\mu A^\alpha$ acts like a free field by suitable boundary condition, by choosing suitable boundary condition.

(Refer Slide Time: 04:57)

You can set $\partial_\mu \partial^\mu A^\alpha = 0$ classically, which is equivalent to the Lorenz gauge. So, if you choose this Lorenz gauge that $\partial_\mu \partial^\mu A^\alpha = 0$ throughout this space time. Then this is equivalent to saying that you actually restrict yourselves to the

Maxwell Lagrangian, but this is all classically, quantum mechanically it is A not substitute forward.

We will see what this equation here simply implies that the conjugate momentum to the field A_β , which I will denote by π_β is given by $-\dot{A}_\beta - \lambda \partial_\mu A^\mu$ with a factor of λ . So, this is the conjugate momentum to the field A_β you see that π_0 specially is no longer zero. So, as such you they not have any difficulty in considering the equal time commutation relations, which are given by $[A_\mu(x), \pi_\nu(y)]$ is basically $i \delta_{\mu\nu} \delta^3(x-y)$.

(Refer Slide Time: 06:31)

So, as an operator equation you can consider this equal time commutation relation, but you can see that π_0 from this equation is basically $-\dot{A}_0 - \lambda \partial_\mu A^\mu$. So, π_0 is simply minus λ times $\partial_\mu A^\mu$. So, you cannot set $\partial_\mu A^\mu = 0$ as an operator equation quantum mechanically. It will be inconsistent to just set this to be 0, because if you set this to be 0. Then the equal time commutation relation you will have for sum this terms you will have the left hand side 0, but the right hand side is not 0.

So, this is going to pose a problem that we will see how to solve this. Therefore, as an operator equation we cannot impose the condition that $\partial_\mu A^\mu = 0$. So, we will see how actually we will what is the physical condition that we have to impose. So, that we restrict ourselves to the Maxwell's theory. That is what we will discuss in a

moment, but before this we will just carry on with A what we have learnt. So, then we will start quantizing.

So, the equation of motion is $\square A_\beta - \lambda \partial_\alpha A_\alpha = 0$. As I say this although we can consider this λ to be any arbitrary parameter. It will simplify much if you if we choose this parameter λ to be 1, because for when we restrict ourselves to the ourselves to the choice $\lambda = 1$. Then the equation of motion becomes $\square A_\beta = 0$ and we know how to handle this equation. So, we will we will solve this equation.

This restriction of this parameter $\lambda = 1$ is known as the Feynman gauge. So, we work in the Feynman gauge for, which the equation of motion is simply $\square A_\beta = 0$. So, this almost looks like again the claim Jordan mass less claim Jordan equation for each of these fields A_β . So, we know how to solve this equation exactly, there will be four linearly independent solution. Now, because we are no longer doing any kind of gauge fixing here, therefore here A_β will go like some $\epsilon_{\beta\mu}(k) e^{-ik \cdot x}$.

So, let us lets parameterize this four linearly independent polarization to be $\epsilon_{\lambda\mu}(k)$ λ varies from 0, 1, 2, 3; just like in the previous case. When we have done when we had performed the gauge fixing, we had 2 linearly independent polarization. We had two transverse polarizations and those we denoted by $\epsilon_{r\mu}(k)$ with $r = 1$ and 2. Here, there will be four linearly independent polarizations two of them are transverse polarizations. The remaining two are known as the longitudinal polarization, as well as the scalar polarization. So, $\epsilon_{0\mu}(k)$ is known as the scalar polarization and $\epsilon_{3\mu}(k)$ is the longitudinal polarization. The most general solution for the field A can be written as $A_\mu(x, t)$ is again in terms of the four real components.

(Refer Slide Time: 12:03)

You will have sum over lambda as where is 0 to 3 and integration over d cube k over 2 pi cube to k 0 times epsilon lambda mu of k A lambda k e to the power minus i k dot x plus epsilon lambda star mu of k A lambda dagger of k e to the power i k dot x. Here, k 0 in this integration is given by mode k. Because, this is a mass less field this is the most general solution.

Now, we are considering this a mu to be a quantum field, therefore these operators, now we can look at the canonical commutation relations. Then we can see what to the mean in terms of these operators A and A dagger. So, what in this gauge lambda equal to 1 the conjugate momentum pi beta is given by minus f 0 beta minus eta 0 beta del mu A mu. You can see that this implies A dot mu of x t A nu of y t the commutator of A dot and A is given by i eta mu nu delta of x minus y. Whereas, A dot mu of x t A nu of y t A mu dot of y t is equal to 0, similarly A mu of x t a nu of y t equal to 0.

So, this is the set of equal time commutation relations, we can substitute this here. Then we can see what do we get in for the creation for the operators A and A dagger before to do that we will make a choice for the polarizations. First of all we will assume that the epsilons are real.

(Refer Slide Time: 16:03)

So, epsilon mu lambda of k is real and we will choose these polarizations such that. Suppose, n hat is unit vector along the time direction, then we will make our choice such that epsilon epsilon 0 mu is equal to n hat mu. Then we will choose epsilon three mu of k to be the vector, which lies in the t k x 0 plane or in the n mu hat k mu. This A plane and this is one linearly independent vector in this plane spin by n hat and k mu. You choose epsilon three to be the unit vector, which is orthogonal to n hat mu, which lies in this plane. So, that is the choice for epsilon 3, epsilon 1 and epsilon 2 are two linearly independent vectors, which are orthogonal to each other, which are orthogonal to this plane

I mean let say your time is along x 0 direction and let us assume that k is along x 3 direction. Then these four linearly independent vectors are simply epsilon 0 is equal to 1 0 0 0 epsilon 1 is a 0 1 0 0 epsilon 2 to be 0 0 1 0 and epsilon 3 to be 0 0 0 1. I mean not exactly k mu, but you just look at A. I mean you can this is just one choice that I have given you need not restrict yourselves to four linearly independent.

(Refer Slide Time: 19:17)

In general they will satisfy this equation that is A given by sum over lambda epsilon lambda mu of k epsilon lambda nu of k star. You do not have to choose them to be real and epsilon alpha lambda k epsilon beta lambda k eta alpha beta. This is eta mu nu and epsilon lambda mu epsilon lambda prime mu eta mu nu is eta lambda lambda prime with A star.

So, with this choice for the polarizations we can look at the equal time commutation relations. You can simply substitute the mode expansions in these equations. Then you can show the I mean this is almost identical to the free scalar field case, except for the presence of these vectors here the polarization vectors. Now, we are making this particular choice for the polarizations. Then you can substitute them and you can show that the operators a and a daggers satisfy the following relation, a lambda of k a lambda prime dagger of k prime is given by minus 2 pi cube 2 k 0 eta lambda lambda prime delta of k minus k prime.

(Refer Slide Time: 21:10)

$$[a^{(\lambda)}(\vec{k}), a^{(\lambda')\dagger}(\vec{k}')] = -(2\pi)^3 \delta^3(\vec{k} - \vec{k}') \eta^{\lambda\lambda'}$$

$$[a^{(\lambda)}(\vec{k}), a^{(\lambda')\dagger}(\vec{k}')] = 0, \quad [a^{(\lambda)\dagger}(\vec{k}), a^{(\lambda')\dagger}(\vec{k}')] = 0$$

$$a^{(\lambda)}(\vec{k})|0\rangle = 0 \quad \text{for } \lambda = 0, 1, 2, 3, \text{ and } \forall \vec{k}$$

$$|1\rangle = \int \frac{d^3k}{(2\pi)^3 2k^0} f(\vec{k}) a^{(\lambda)\dagger}(\vec{k})|0\rangle$$

$$\langle 1|1\rangle = \int \frac{d^3k}{(2\pi)^3 2k^0} \frac{d^3k'}{(2\pi)^3 2k'^0} f^*(\vec{k}') f(\vec{k}) \langle 0| a^{(\lambda)}(\vec{k}) a^{(\lambda)\dagger}(\vec{k}')|0\rangle$$

Whereas, a lambda k a lambda prime k prime equal to 0 and show is a lambda dagger of k a lambda prime dagger of k prime. This is what we get for the commutation relations for the a s and a daggers. So, you can again interpret these a s to be the annihilation operators a daggers to be the creation operators. You can define their vacuum to be the one, which is annihilated by a lambda k for lambda equal to 0, 1, 2, 3. For all k then the one particle states two particle states etcetera will be obtained from the vacuum by acting the creation operators submit.

So, you might think that everything is perfectly all right you have now the whole spectrum. Then you can consider the Hamiltonian and then what are the n and j Eigen values and so on, but it is not so simple. The reason is the following you look at the one particle states, which correspond to the let say scalar polarization. So, folks space of one prime states are usually of this form. That you just consider the cube k over 2 pi cube to k 0 sum distribution in the momentum space f of k a lambda dagger of k acting on the vacuum. So, a typical one particle state, which has a finite spread in the momentum space looks like this. You consider such a state for the scalar polarization. So, you just set a lambda equal to.

So, you just consider the case when lambda equal to 0 and then look at the norm for this one particle state. So, what do you get for the norm of this one particle state. So, this will be the d cube k prime over 2 pi cube 2 k 0 prime. Then you have f star of k prime f of k

then a lambda I am considering the one particle state corresponding to this scalar polarization. So, a lambda acting on k prime a 0 dagger k this is what is the norm for the one particle state. Now, I can use this commutation relation to flip this a and a dagger here, but when I do that what I get is the following. So, a 0 k prime a 0 dagger of k is basically the commutator of a 0 k prime a 0 dagger of k and plus a 0 dagger of k a 0 of k prime.

(Refer Slide Time: 26:29)

$$\begin{aligned}
 & \langle 0 | (i\vec{k} \cdot \vec{a}^\dagger(\vec{k})) | 0 \rangle \left(a^\dagger(\vec{k}), a^\dagger(\vec{k}') + a^\dagger(\vec{k}) a^\dagger(\vec{k}') \right) | 0 \rangle \\
 & \langle 1 | \rangle \\
 & = \int \frac{d^3k}{(2\pi)^3 2k} \frac{d^3k'}{(2\pi)^3 2k'} \langle 0 | (-i\eta)^2 2k \delta(\vec{k}-\vec{k}') | 0 \rangle f(\vec{k}) f^\dagger(\vec{k}') \\
 & = - \langle 0 | 0 \rangle \int \frac{d^3k}{(2\pi)^3 2k} |f(\vec{k})|^2 < 0
 \end{aligned}$$

Now, I will substitute this in the expression for the norm of this one particle state corresponding to the scalar polarization. When I substitute that the contribution from this term vanishes, because I am considering this inside this. So, therefore you have a vacuum here and there is a ground state acting on this is an annihilation operator. It will just when acting on the ground state it will give you 0. So, this term vanishes therefore, what we get for the norm here is d cube k over 2 pi cube 2 k 0 d cube k prime over 2 pi cube 2 k 0 prime. This the commutator here, but what is the commutator? If you look at the commutator its minus 2 pi cube 2 k 0 eta lambda lambda prime.

So, for lambda equal to 0 and lambda prime equal to 0, it will give you minus 2 pi cube 2 k 0. Because, of this minus sign here you have a minus 2 pi cube 2 k 0 times delta k minus k prime, this is all you get. It has zero, 0 is one, therefore this is what we have. Now, you can perform the k prime integration and then there is f of k f star of k prime. If

you perform the k prime integration what you get is norm of the ground state. There is a minus sign integration $d^3 k$ over $2\pi^3$ k_0 mode f of k square.

So, what you saw here is that the norm of this one particle states are negative, therefore when you quantize when you consider this theory. Then you quantize it you see that there are negative norm states present in the Hilbert space. Therefore, you this is of course, a problem you need to get it off all this negative norms state. So, need to consider how to consider, how to impose a physical condition, which will remove all the negative norms states from the Hilbert space. Remember, we had avoided one of the issues earlier, which was the condition setting the condition $\partial_\mu a^\mu = 0$.

(Refer Slide Time: 30:44)

If we set this as an operator equation, then we run into inconsistency. In the sense that the canonical commutation relations that we have adapted cannot be satisfied, if we consider this as an operator equation left hand side becomes zero, but its right hand side none 0 and so on. So, we need to worry how to impose this condition also in order to recover the Maxwell's theory. What we will see is that we will see the states in the Hilbert space are physical. If they satisfy this condition that suppose ψ is A state for which $\partial_\mu a^\mu$ the expectation value of this operator in this state is 0.

(Refer Slide Time: 31:35)

Then this is a physical state. So, this is the physical state condition that that we are going to impose. Although, we cannot set $\partial_\mu A^\mu$ equal to 0 as an operator equation. We can consider the expectation value of this operator in any arbitrary state. Then we will require that this expectation value is always 0. So, we are saying that state is a physical state if it satisfies these conditions that expectation value of $\partial_\mu A^\mu$ equal to 0. Otherwise, it is not a physical state. Then we will see what is the implication of this physical state condition?

We will see that this physical state condition not only will give us the Maxwell's theory. It will also remove all the unwanted negative norms states that appear in this spectrum here. So, the physical Hilbert space will not content of any of these negative norm states, that is what we will see in a moment. So, this condition here is equivalent to imposing this that to $\partial_\mu A^\mu$ plus acting on this state ψ equal to 0. You can see that this specially implies this one.

So, let us look at this condition here A^μ plus contents the positive frequency part of A the mode expansion. Therefore, A^μ plus of x according to our definition is $d^3k / (2\pi)^3 \sum_{\lambda=0}^3 \epsilon_{\lambda\mu}(k) a_{\lambda}(k) e^{ik \cdot x}$.

(Refer Slide Time: 33:00)

$$A^+(\mathbf{x}) = \int \frac{d^3k}{(2\pi)^3 2k^0} \sum_{\lambda=0}^3 \epsilon_{\mu}^{(\lambda)}(\mathbf{k}) a^{(\lambda)}(\mathbf{k}) e^{-ik \cdot x}$$

So, what do we get when I impose this condition here? When I impose the condition that this quantity acting on some state gives you 0, so to do that lets consider a basis in the Hilbert space, which is given by this form a basis of states, if I can choose a basis of states, which are of this form ψ and ϕ .

(Refer Slide Time: 34:37)

$$\langle \psi | \partial_{\mu} A^{\mu} | \psi \rangle = 0$$

$$\partial_{\mu} A^{\mu} | \psi \rangle = 0$$

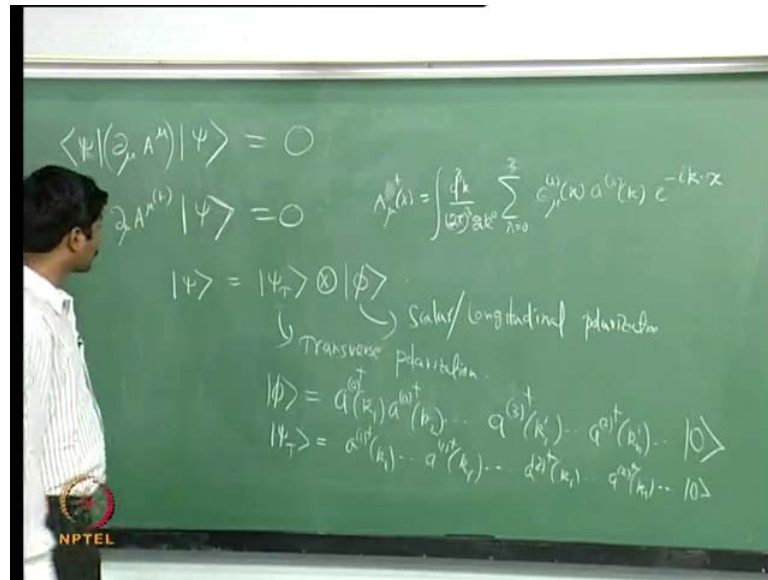

$$A^+(\mathbf{x}) = \int \frac{d^3k}{(2\pi)^3 2k^0} \sum_{\lambda=0}^3 \epsilon_{\mu}^{(\lambda)}(\mathbf{k}) a^{(\lambda)}(\mathbf{k}) e^{-ik \cdot x}$$

$|\psi\rangle = |\psi_{\perp}\rangle \otimes |\phi\rangle$
 ↳ Transverse polarization. ↳ Scalar/longitudinal polarization.
 $|\phi\rangle = a^{(0)}(\mathbf{k}) a^{(1)}(\mathbf{k})$

Do you understand what is this ψ correspond to the states, which I raise due to the transverse polarization, whereas this ϕ here correspond to the longitudinal and scalar polarization. So, this is a scalar or this correspond to transverse polarization. So, this now

what we get is we will see what happens, when A_{μ}^{+} acts on a state like this, because this corresponds to this scalar polarization. Therefore, this state ϕ here will be of this form it will be obtained by a $a_{0k}^{\dagger} a_{0k}^{\dagger} a_{0k}^{\dagger}$. There will be a number of a_0 operators.

(Refer Slide Time: 36:23)

Then there will be a number of $a_{3k_1}^{\dagger} a_{3k_2}^{\dagger} \dots a_{3k_n}^{\dagger}$ acting on the ground state here. So, a general n particle state corresponding to this will have n such operators here. Whereas, this ψ_{\perp} here is just given by again this state ψ_{\perp} will be of this form, where you have transverse polarization $a_{1k_1}^{\dagger}$ and $a_{1k_r}^{\dagger}$ number of such operators. Then you will have also $a_{2k_1}^{\dagger}$ and $a_{2k_n}^{\dagger}$ acting on the translate here. Now, what happens is that, now what we will see what a_{μ}^{+} acting on this state ψ_{\perp} and ϕ equal to 0 gets itself, this is there is this $\delta_{\mu} a_{\mu}$ acting on this.

(Refer Slide Time: 38:09)

$$\begin{aligned} \frac{d}{dk} \hat{A}_\mu^{(\lambda)}(k) |\psi_T\rangle \otimes |\phi\rangle &= 0 \\ \int \frac{d^3k}{(2\pi)^3} (-i) \sum_{\lambda=0}^3 k_\mu \epsilon^{(\lambda)}(k) a^{(\lambda)}(k) e^{-ik \cdot x} |\psi_T\rangle \otimes |\phi\rangle &= 0 \\ \int \frac{d^3k}{(2\pi)^3} (-i) (a^{(0)}(k) - a^{(3)}(k)) e^{-ik \cdot x} |\psi_T\rangle \otimes |\phi\rangle &= 0 \end{aligned}$$

So, what do you get from here as you can see this $\frac{d}{dk}$ over $2\pi^3 k_0$. This derivative acting on this will give me sum over λ equal to 0 to 3 $k_\mu \epsilon^{(\lambda)}(k) a^{(\lambda)}(k) e^{-ik \cdot x} |\psi_T\rangle \otimes |\phi\rangle = 0$. Now, because of this appearance of this k_μ here the transverse polarization will simply go away, because for λ equal to 1 and 2 this is simply 0. Although, λ is summed over all the values λ equal to 1 and 2, correspond to transverse polarization.

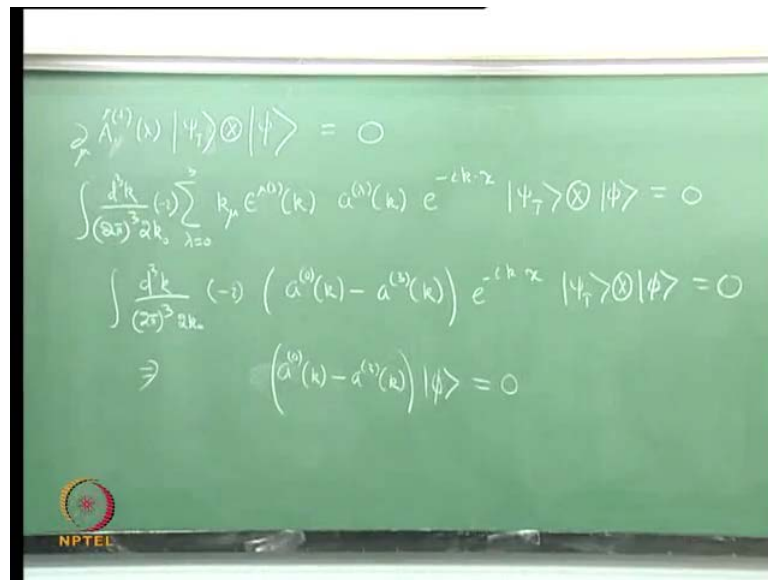

So, this simply kills the λ equal to 1 and 2. Therefore, what is left here is a $\frac{d}{dk}$ over $2\pi^3 k_0$. There is a minus i and then a 0 of $k_0 - k_3$ times $e^{-ik \cdot x}$, is this clear? This λ equal to 1 and 2 just goes away and $k \cdot \epsilon$ just gives you this minus sign here, k is just a null vector and k you can choose to be something like $(1, 0, 0, 1)$.

(Refer Slide Time: 42:01)

Then this will simply imply if according to our choice epsilon 0 is just a 1 0 0 0. Whereas, epsilon 3 0 0 0 1 and then this factor will simply gave you this, because this involves only the scalar and longitudinal polarization. It's irrelevant to consider this transverses part here.

(Refer Slide Time: 42:39)

So, these simply imply that a 0 k minus a 3 k acting on some n particles state gives you 0. So, this is what is equivalent to imposing this condition del mu a mu plus on this state

psi equal to 0. Let say consider the number operator corresponding to this scalar and longitudinal polarization.

(Refer Slide Time: 43:32)

You can work out the expression for the number operator you can show that the number operator is simply $\int d^3k / (2\pi)^3 2k_0 a^\dagger(\mathbf{k}) a(\mathbf{k})$. I think there is a 3 here, there is a 3 here minus a $0 k_0 a^\dagger(\mathbf{k}) a(\mathbf{k})$. This is the number operator corresponding to the longitudinal and scalar polarization. You can look at some n particles state $|\phi\rangle$ any arbitrary state $|\phi\rangle$ here can be express as sum coefficient c_n times $|\phi_n\rangle$ summed over n, where $|\phi_n\rangle$ here is n particles state corresponding to this scalar and longitudinal polarization. So, there will be a 0 daggers and a 3 daggers and there will be n such objects acting on the vacuum. That is what I am denoting by $|\phi_n\rangle$ and a $|\phi\rangle$ in general is summed over all these things.

(Refer Slide Time: 45:17)

So, now if you look at this quantity here you can show that this $2k_0$ and a 3 dagger k a three of k minus a 0 dagger k a 0 k ϕ_n here, but now this ϕ_n satisfies this condition, that a 0 acting on ϕ_n is equal to a 3 acting on ϕ_n . So, I can use that relation when I used that this will become ϕ_n d^3k over $2\pi^3 2k_0$. This is a 3 dagger k minus a 0 dagger of k a 0 of k acting on ϕ_n . Suppose, ϕ_n is not equal to ϕ_0 suppose ϕ_n of course, in general it will have c_0 times ground state plus c_1 times one particles state and so on.

(Refer Slide Time: 47:09)

In general ϕ_n will have something, so suppose n is not 0 if n is not 0 then this is not ground state. So, in that case what you can see is that this quantity here is simply equal to 0, because you can consider this acting on this is simply this is always equal to 0, this quantity here is always equal to 0. This is, because if n is ground state then it of course, it annihilates ground state even if n is not equal to ground state you can consider this. Then this when it acts on this one, from the right again you can use the conjugate of this equation here. This conjugate shows that this is equal to 0. So, what does it mean? It simply means that if n is the number operator.

(Refer Slide Time: 48:37)

Then n acting on ϕ_n is just n times ϕ_n right, but this calculation shows that this is equal to 0. Therefore, ϕ_n , which is n times ϕ_n , which is equal to 0.

(Refer Slide Time: 48:52)

Basically, implies that $\langle \phi_n | \phi_n \rangle = 0$, when n is not equal to 0. In other words if n is not equal to 0 this is just a ground state, which is unique norm, therefore this quantity is δ_{n0} . Therefore, if you consider an arbitrary state corresponding to scalar and longitudinal polarization, which satisfy this condition here, then this state can either be ground state or it will have a 0 norm.

So, these are all null states except for the ground state all the n particle states corresponding to this scalar and longitudinal polarization, which satisfy the physical state condition are all null state. Then you can see that if you consider any physical observable and then if you compute the expectation value. For example, let say you consider the Hamiltonian of the theory.

Then you compute the expectation value of the Hamiltonian in the physical Hilbert space, then these states these null states completely decoupled. They just drop out from the expectation values that is what you can see when you do in an explicit computation. So, although these states are there they do not contribute to any physical measurable quantity. We have said the physical Hilbert space is formed by states of this type ψ and ϕ .

(Refer Slide Time: 50:39)

These involve the transverse polarization whereas, these involve the scalar polarization. However, not all these states in the in the full Hilbert space satisfy the physical state condition, which is given by $\text{div } A^+ \psi = 0$. For example, we have considered the state the one particle state, which is given by $|1\rangle = \int \frac{d^3k}{(2\pi)^3 2\omega} f(k) a^{\dagger}(k) |0\rangle$. Then we have seen that this state has negative norm the norm of the state is less than 0.

So, this state for example does not satisfy the physical state condition $\text{div } A^+ \psi = 0$ any state of this type, which is ψ_T . If you consider any state of this type, which is actually given by the creation, which is actually generated by acting creation operators for the transverse polarizations, which is $a^{\dagger 2}(k)$, so on a $a^{\dagger 1}(k')$ and so on like this.

So, states of this type do satisfy the physical state condition. So, they are they are in the physical Hilbert space there are other states. For example, states like this they do not satisfy the physical state condition. So, they do not belong to the physical Hilbert space. However, in addition to these states there are a bunch of states, which are also generated by this scalar. So, which are of this type $a^{\dagger 0}(k)$ acting on this or a $a^{\dagger 3}(k)$ acting on this or a bunch of operators, like $a^{\dagger 0}(k) a^{\dagger 3}(k)$, so on acting on the state.

(Refer Slide Time: 53:08)

$$|\varphi_n\rangle = a^{(1)\dagger}(k) \dots a^{(n)\dagger}(k) \dots |0\rangle$$
$$\langle \varphi_n | \varphi_n \rangle = 0$$
$$a^{(1)\dagger}(k) |0\rangle$$
$$a^{(2)\dagger}(k) |0\rangle$$

So, φ_0 I will call them φ_n these are the n particle states, which have 0 norms. So, $\langle \varphi_n | \varphi_n \rangle$ norm of these states are 0. There are a bunch of states, which are generated by acting these operators on the vacuum with 0 norm, this will be there in the physical Hilbert space however, because these states have 0 norm. Therefore, you consider any observable quantity expectation values of any operator. These states do not contribute at all. It is only these states, which are generated by acting the transverse on the by acting the creation operators corresponding to the transverse polarizations. They only generate the physical Hilbert space.
