Introduction to Classical Field Theory

(Refer Slide Time: 00:16)

Today we will discuss Euler-Lagrange equations. And then we will discuss symmetric and conservation laws, and now the theorem so on the Euler-Lagrange and Noether theorem. So, just like in mechanics you start with the action which is integration of the Lagrangian with respect to time. But the Lagrangian L here is a taken to be integration of something which is called this is the Lagrangian density over the entire space; here this curly L is known as the Lagrangian density, L of phi Del mu phi is known as the Lagrangian density. And it is a functional of the field phi and its derivative.

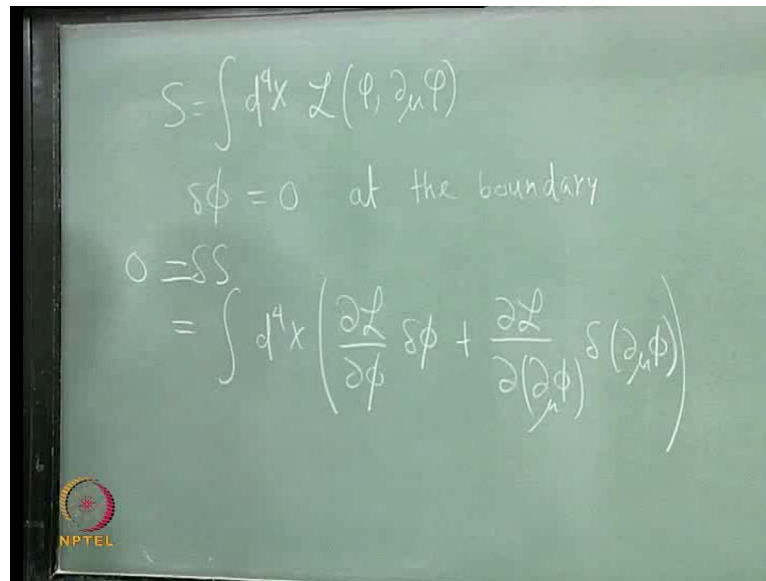

(Refer Slide Time: 02:00)

This field ϕ here in this case depends on what system we are describing; for example, if we consider a system of electron magnetic fields then the field ϕ is a gauge field A_μ which is nothing but the vector potential \vec{A} and scalar potential there is also denoted as ϕ . If you consider let say electromagnetic field interacting with ϕ or some other complex field; then in this case the field in question is a complex scalar field ϕ it is complex conjugate ϕ^* . And the electromagnetic field A_μ ; if you consider electron interacting or electron interacting with electromagnetic field then the field in this question is A_μ and ψ which represents the field for an electron.

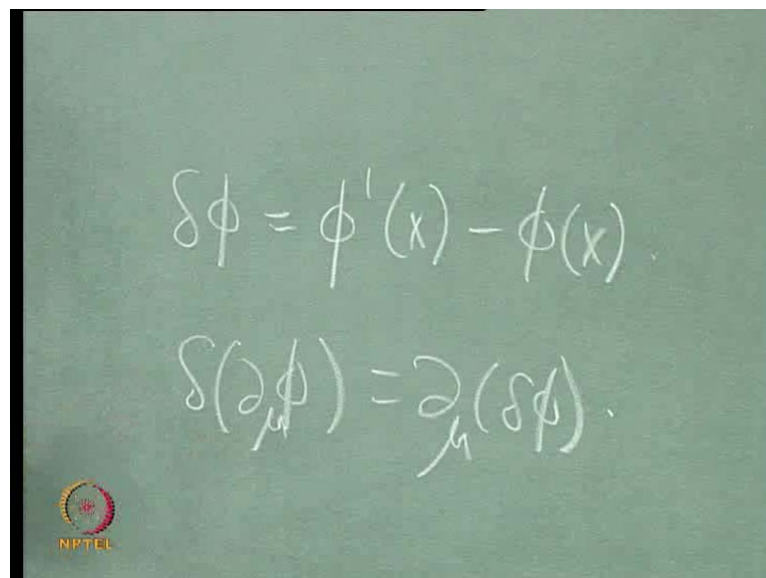

So, depending on the system we have the field ϕ and its derivative $\partial_\mu \phi$; in general the Lagrangian density can contain finite number of derivatives our most of the system that we study in physics involve only 1 derivative of the field here. So, I will consider the Lagrangian density to be functional of the field ϕ . And all this first derivative then ϕ here I should explain what this notation means; the special coordinate I take them to be x^μ to be x . And t where x denotes the special variables and t is the time; x^0 is represented x^t and x^i at the i components of this x so this index μ here density 0, 1, 2, 3, 4 variables.

(Refer Slide Time: 04:24)

$$S = \int d^4x \mathcal{L}(\phi, \partial_\mu \phi)$$
$$\delta\phi = 0 \text{ at the boundary}$$
$$0 = \delta S$$
$$= \int d^4x \left(\frac{\partial \mathcal{L}}{\partial \phi} \delta\phi + \frac{\partial \mathcal{L}}{\partial (\partial_\mu \phi)} \delta(\partial_\mu \phi) \right)$$

So, I will take this action from this we can see that the action is actually d^4x times the Lagrangian density of ϕ and $\partial_\mu \phi$; we will vary this action by keeping the fields variations of the field $\delta\phi$ equal to 0 at the boundary. And this will give me the field equation. So, let us do that. So, δS by setting δS to be 0 is equal to integration over d^4x , $\frac{\partial \mathcal{L}}{\partial \phi} \delta\phi + \frac{\partial \mathcal{L}}{\partial (\partial_\mu \phi)} \delta(\partial_\mu \phi)$; at given point $\delta\phi$ is basically $\phi(x) - \phi(x')$.

(Refer Slide Time: 05:44)

$$\delta\phi = \phi(x) - \phi(x')$$
$$\delta(\partial_\mu \phi) = \partial_\mu(\delta\phi)$$

So, as you can see the variation does not depend on same point. So, therefore delta and Del mu can commute. So, I can write delta of delta mu phi is Del mu of delta phi; I will substitute this here and then I will do some rearrangement.

(Refer Slide Time: 06:26)

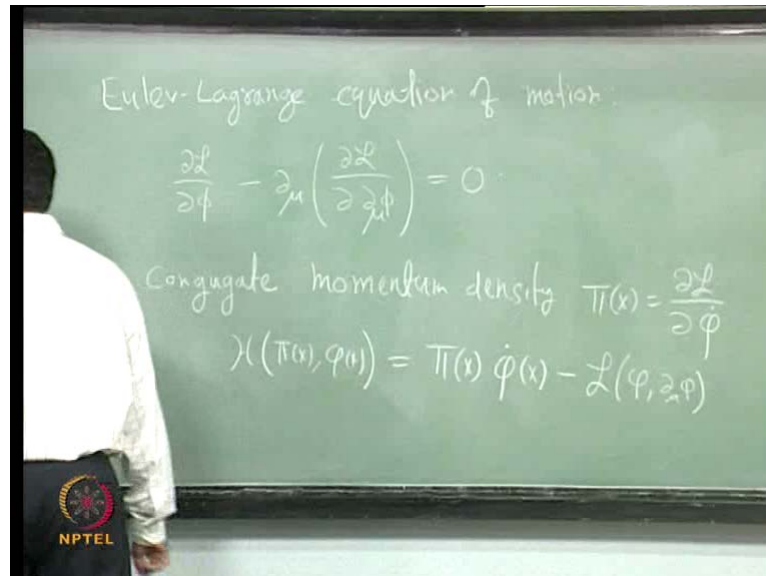

So, that will give me delta of s equal to integration d 4 x; Del L over L phi delta phi plus Del L over Del of del mu phi Del mu of delta phi. Now, what I will do is I will take this second term and then I will write it as a total derivative minus some quantity; as you can see the second term can be written as del mu of del L over del, del mu phi times delta phi minus del mu of del L over del, del mu phi times delta phi. I will substitute this here and when I substitute what I get is delta S is equal to integration d 4 x; I will collect the term which come with the factor of delta phi together. And then I will write it is delta phi times Del L over Del phi. And this term here minus Del mu of Del L over Del mu phi; then I have this term plus del mu of L del L over del, del mu phi times delta phi.

Now, you can see the second term is total derivative. So, we can use gauss diversion theorem and then we will get and integration at the boundary; however, we have we require that the variation of the field at the boundary vanishes. So, therefore the contribution of this total derivative term is 0. And hence the variation of action actually depends on some term which is multiplied by delta phi delta phi is arbitrary is infinite this variations. And hence delta S will be 0; if and only if the quantity here in the bracket

is 0. Hence, by varying the action we got the Euler-Lagrangian equation which is this quantity inside the bracket equal to 0.

(Refer Slide Time: 09:54)

So, the Euler-Lagrange equation of the motion is given by $\text{Del } L \text{ over Del } \phi \text{ minus Del } \mu \text{ Del } L \text{ over Del } \mu \phi$ is equal to 0. Now, we also need to introduce conjugate momentum and Hamiltonian in order to quantize; we will quantize the canonical way just the way you quantize in non relativistic quantum mechanics, you consider the coordinate variable. Then you consider the corresponding conjugate momentum; you start with the Kevin Gordon and relations and quantize the theory this will do exactly in the same way. And hence we need to introduce the conjugate momentum correspond to the field ϕ .

So, the conjugate in this case; what you will have is the momentum density. So, conjugate momentum density π of (x) is equal to $\text{Del } L \text{ over Del of } \dot{\phi}$. Then the Hamiltonian density H of (x) is define to be $\pi \dot{\phi}$; note that $\dot{\phi}$ here the dot represent derivative with respect to time minus L of (ϕ) the Hamiltonian density is define to this. Now, what we will do is; we will discuss Noether theorem in somewhat detail. So, Noether theorem states that for every continues symmetry there is a corresponding conserve quantity; we will explain what, when we call a quantity to be conserve as we go on.

(Refer Slide Time: 12:44)

So, let us start with the Noether theorem; the statement is that continuous symmetry implies conservation law. When do we say that the symmetry theory? You consider the field ϕ of (x) suppose you make a transformation the field goes to some transformed field ϕ' of (x') . If the equation of motion has the same form if the form of the equation of motion does not change; then you say that this transformation of the field ϕ of (x) to ϕ' of (x') is actually a symmetry of the theory.

So, form of the equation of motion remains invariant implies you have a symmetry; this will happen if the action when S remains invariant under this transformation. So, you make this transformation and then if the action does not change under this transformation then classically you have the symmetry with the theory. In this case what we will discuss is we will discuss continuous symmetries; the symmetry transformations the set of symmetry transformations which are actually parameterized by continuous parameters these are known as the continuous symmetries.

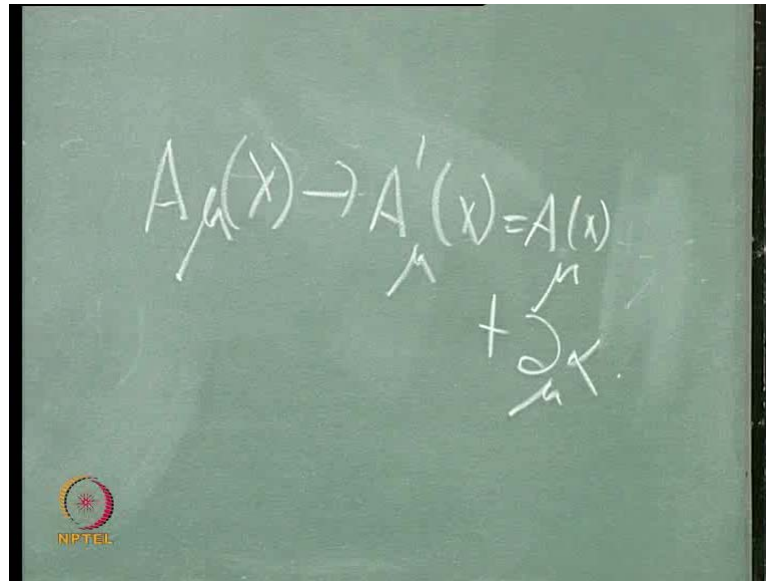

So, what we will see what happens when the system remains invariant under a continuous symmetry. Now, the theorem states that continuous symmetries imply a conserved quantity and this is what we will see in the subsequent discussion. So, what kind of symmetry transformations that we come across in physics, mostly we will discuss relativistic quantum field theory.

(Refer Slide Time: 15:58)

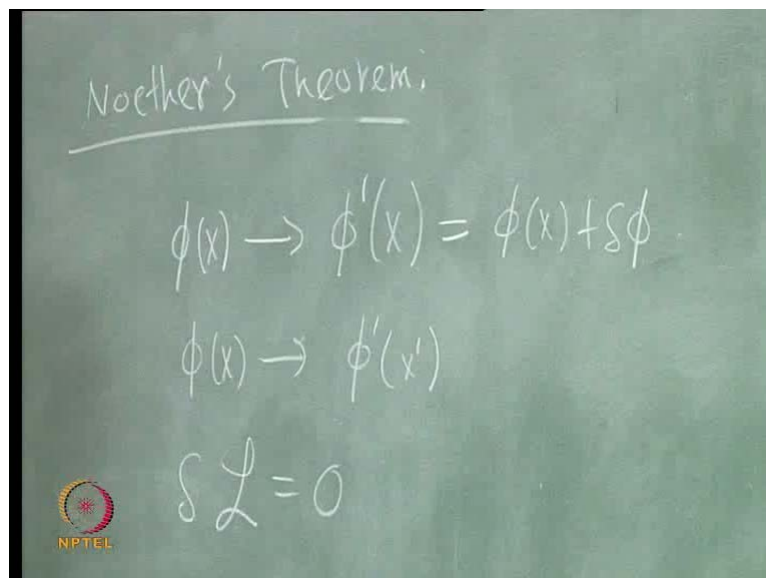

So, we keep seeing Lorentz transformation where the space time coordinates actually change like x^μ going to $\Lambda^\mu_\nu x^\nu$, x^μ this is also known as the homogenous Lorentz transformation; we have in homogenous Lorentz transformation or Poincaré transformation this is Lorentz transformation flows a translation. So, x^μ under Poincaré transformation goes to $\Lambda^\mu_\nu x^\nu + a^\mu$; also in electro dynamics you see there are this vector potential A and scalar potential ϕ . And if you make the transformation such that A goes to A' ; which is A plus gradients of some scalar which I will call as α . And if ϕ goes to ϕ' which is ϕ plus $\text{Del } \alpha$ over $\text{Del } t$; I am not sure about the minus sign I think this is minus sign here. Then the electric and magnetic field E and B in the mention variant unlike this transformation does not depend on these wave parameters. So, this happens at the same point, at the same special point at same time.

(Refer Slide Time: 18:14)

$$A_{\mu}(x) \rightarrow A'_{\mu}(x) = A_{\mu}(x) + \partial_{\mu} \alpha(x)$$

So, x and t , x and t so; this is known as the gauge transformation; in 4 vector notation I can write it as A_{μ} the 4 vector A_{μ} . And under this transformation goes to strictly speaking A_{μ} of (x) goes to A'_{μ} of (x) which is A_{μ} of (x) plus $\partial_{\mu} \alpha$. So, this happens at the same point in this space time this is an internal symmetry transformation. So, you have Poincare transformation and you also have internal symmetry under this transformation also the equation of motion in electro dimension remains invariant.

(Refer Slide Time: 19:16)

Noether's Theorem,

$$\phi(x) \rightarrow \phi'(x) = \phi(x) + \delta \phi$$
$$\phi(x) \rightarrow \phi'(x')$$
$$\delta \mathcal{L} = 0$$

So, there are such transformations; we will discuss what happens under such transformation under internal symmetry transformation ϕ of (x) ; the field ϕ of (x) goes to ϕ' of (x) which is equal to ϕ of (x) plus some $\delta\phi$. If I consider infinity transformation then this is what I get more generally the field of (x) will transformed to some ϕ' of (x') where both the field as well as the arguments says under this transformation. So, this will be combination of some internal symmetry transformation as well as the point transformation; what we will do is that will first consider this second similar case. And then we will see how do we get conservation laws under such a transformation; then we will discuss about the second possibility which is much more general than this one.

So, let us consider the variation here strictly speaking we should require the action to be invariants under such transformation; what we will do is that will restrict our self to the special case where the Lagrangian density remains invariants under such transformations. If the Lagrangian density remains invariant then; obviously, the S is invariant however, the Lagrangian density can actually saying up total derivative. And if the fields when it sufficiently first infinity then also the action will remain invariant; we will not worry about this second possibility here. So, we will consider the case where the Lagrangian density L remains invariant under such transformation.

(Refer Slide Time: 21:22)

$$\delta L = \left(\frac{\partial L}{\partial \phi} \right) \delta \phi + \left(\frac{\partial L}{\partial \phi_r} \right) \delta \phi_r$$

So, δL is 0 under such transformation what is the δL ? δL is nothing but $\partial_\mu L \delta\phi + \partial_\nu L \delta x^\nu$; we will consider the field configurations which obey the classical field equation, the Euler-Lagrange equations remember here this variation is done at every point in this space time. And we will consider the field consideration with satisfy the Lagrangian equation.

(Refer Slide Time: 22:19)

So, we will use the Euler Lagrangian equation to substitute for the first term here; using Euler-Lagrangian equation we find that $\partial_\mu L$ over $\partial_\nu \phi$ is equal to $\partial_\mu \partial_\nu L$ over $\partial_\nu \phi$. So, this will substitute in the expression for δL to get δL equal to $\partial_\mu \partial_\nu L$ over $\partial_\nu \phi$ times $\delta\phi$ plus $\partial_\mu L$ over $\partial_\nu \phi$ times δx^ν . As you can see again I have exchange δ and ∂_μ ; because this δ transformation here does not depend on x on this space times point x^μ . Now, you can see if you combine both these terms you will get a total derivative. So, this quantity is nothing but $\partial_\mu \partial_\nu L$ over $\partial_\nu \phi$ times $\delta\phi$ this is of the for $\partial_\mu j^\mu$ where this 4vector j^μ is equal to $\partial_\nu L$ over $\partial_\nu \phi$ times $\delta\phi$. So, the invariant of the Lagrangian means that δL equal to 0.

So, if δL equal to 0 then $\partial_\mu j^\mu$ equal to 0 where j^μ is the quantity given by this expression; whenever, this happens you call this quantity j^μ to be a conserved current. So, $\partial_\mu j^\mu$ equal to 0; implies j^μ is a conserve current. So, what we have seen is that if we require the system to be invariant under a continuous internal

symmetry transformation. Then we find an equation we get an equation like this provided the field configuration over the equation of motion. And hence we get a quantity, we get a 4 vector which remains conserve; what do you mean by some quantities which remains conserve we will see it in a moment.

(Refer Slide Time: 25:21)

$$\frac{\partial j^0}{\partial t} - \nabla \cdot \vec{j} = 0$$

$$Q(t) = \int j^0(x,t) d^3x$$

$$\Rightarrow \frac{dQ(t)}{dt} = \int d^3x \nabla \cdot \vec{j} = \int \vec{j} \cdot d\vec{S} = 0$$

Boundary

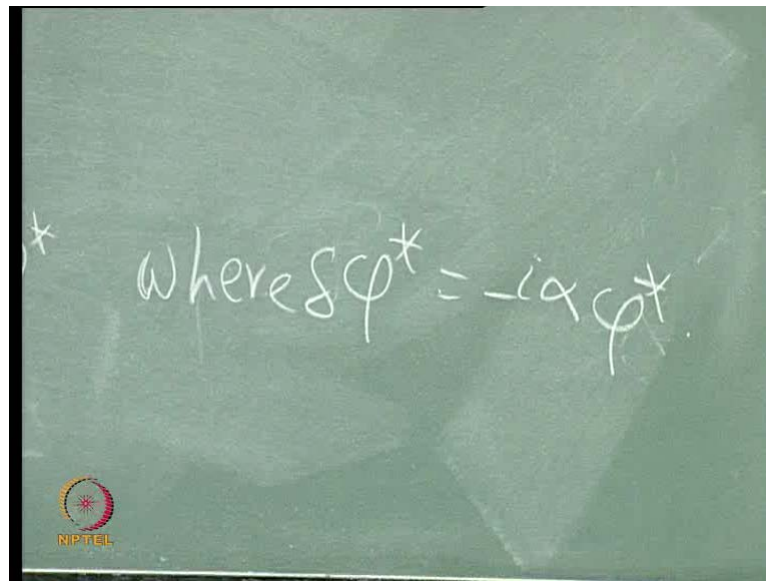

$$\Rightarrow \frac{dQ}{dt} = 0$$

So, let us write this equation in term of components; what we get is $\text{Del } j^0$ over $\text{Del } t$ plus $\text{Del } j^i$ over $\text{Del } x^i$ is equal to 0. Now, I will integrate it over the entire space and I define some quantity which I will call as Q of (t) ; Q of t is define to be integration of j^0 of (x, t) over the entire space d^3x . Then this implies dQ of over $d t$ is equal to minus integration of I think there is the minus here. So, this will be integration of $d^3x \text{Del} \cdot \vec{j}$. And if I use gauze diversions theorem; what I will get is integration of $\vec{j} \cdot d\vec{S}$ at the boundary.

And, if the outgoing flux vanishes or if the fields go to 0 sufficiently fast at infinity then this quantity equal to 0; there for the rate of change of this quantity Q of (t) actually is equal to 0. So, this implies dQ over $d t$ equal to 0. So, this quantity here which I define to the Q remains constant in time. So, what we get is the quantity which remains conserve. So, what I get is $\text{Del } j^0$ plus $\text{Del } j^i$ equal to 0 right. And I am using the matrix which is η_{00} equal to 1, η_{ij} equal to minus delta $i j$ and a $\text{del} \cdot \vec{j}$ in the usual sense in this just $\text{del } j^i$ right.

So that will give you minus sign when this becomes a covariant j_i will require minus sign and here therefore I will have minus sign. So, what we see is that the rate of change of which I have A is actually 0 provided the field and field when this sufficiently first infinity. So, a continuous symmetry implies a conservation law this is what we have seen; we can see a very simple system and then we can construct the discharge for this system.

(Refer Slide Time: 28:44)

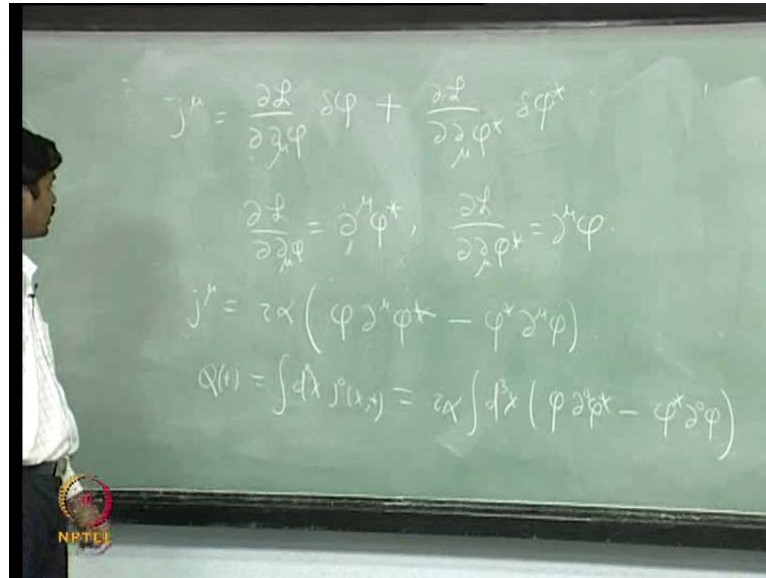

So, let us consider the system of a complex scalar field φ and its complex conjugate φ^* of (x) are linearly independent. And let us consider the Lagrangian to be Lagrangian density L of φ $\partial_\mu \varphi$ to be half $\partial_\mu \varphi \partial^\mu \varphi^*$ minus some potential V of $\varphi^* \varphi$; this Lagrangian density is invariant under a continuous global transformation that is if φ goes to $e^{i\alpha} \varphi$. And hence φ^* goes to $e^{-i\alpha} \varphi^*$; under such a transformation $\varphi^* \varphi$ remains invariant. Therefore, potential term here remains invariant.

And, in the kinetic term α also you get the $e^{-i\alpha}$ from the first term and $e^{i\alpha}$ from the second term. Because α is a constant it does not depend on space time variables and hence the first term also remains invariant. So, such a system is invariant under a continuous global symmetry we will see; what is the corresponding conserved current for such symmetry; we will consider the infinity for

this transformation. So, if I consider infinity smile transformation phi goes to phi plus delta phi over delta phi is i alpha times phi. And phi star here goes to phi star plus delta phi star; which is, where phi star is minus i alpha phi star delta phi star is minus i alpha times phi star.

(Refer Slide Time: 31:27)

So, you will substitute this in our expression for the conserve current j^μ which is given by $\text{Del } L \text{ over Del } \mu \text{ phi time's delta phi}$. In this case we have 2 independent field phi and phi there. So, whenever say there are more than 1 field; we have to sum over the field here. So, in this simple system they conserve current is actually this plus $\text{Del } L \text{ over Del, Del } \mu \text{ phi star delta, delta phi star}$. If there are more than 2 fields than you have to sum over all such fields; from the Lagrangian density you can derive what is $\text{del } L \text{ over del } \mu \text{ phi}$ $\text{del } L \text{ over del } \mu \text{ phi}$ is nothing but $\text{del } \mu \text{ phi star}$ and $\text{del } L \text{ over del, del } \mu \text{ phi star}$ is $\text{del } \mu \text{ phi}$.

So, I will substitute this and also the expression for delta phi then what I see is j^μ is equal to $i \alpha \text{ times phi Del } \mu \text{ phi star minus phi star Del } \mu \text{ phi}$. So, for these very simple systems the conserve current have this expression, it is this expression. And the corresponding stars Q of (t) which is integration $d Q \times j^0(x, t)$ is given by $i \alpha \text{ integration d to x phi Del } 0 \text{ phi star minus phi star Del } 0 \text{ phi}$ all right. So, this is the quantity which remains concert as a continuous of as a consequence of the continuous local symmetry.

(Refer Slide Time: 34:09)

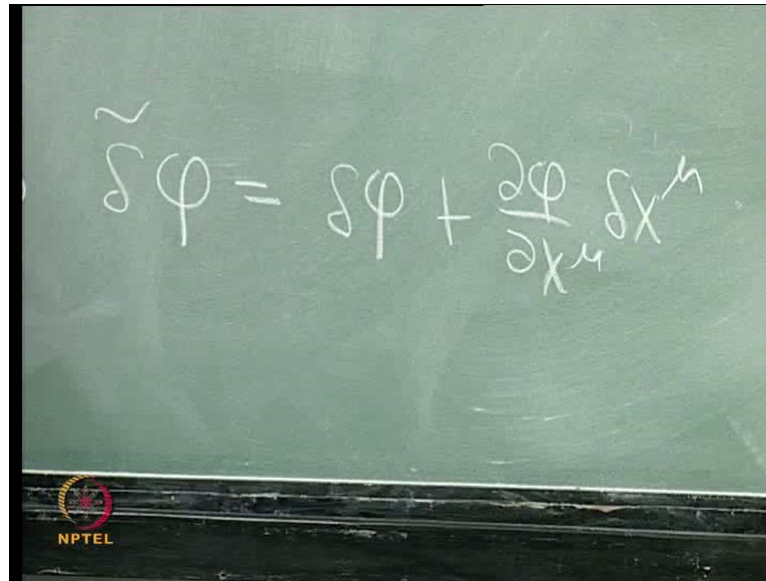

Now, in the remaining part of this lecture; we will consider the more general scenario that is when the field, when the argument of the field. So, φ of (x) goes to φ prime of $(x$ prime) φ prime of we will introduce some variation which I will call as δ till of φ which I will define to be φ prime of x prime minus φ of (x) . In order to distinguish this from the variation of δ of φ which I have introduced earlier which is φ prime of (x) minus φ of (x) we need to keep in mind that in this case we have to require the action to be invariants; it is not sufficient to consider the invariants of the Lagrangian only is the argument of the fields also get transferred.

Let us rewrite this variation δ till of φ in a way which we will need for later purpose. So, δ till of φ can be written as φ prime of $(x$ prime) minus φ prime of (x) plus φ of $(x$ prime) minus φ of (x) . So, what I did is I have added φ of $(x$ prime) and also I have subtracted the same thing. So, I just write in a rewritten form.

However, now you can see that this quantity here is nothing but δ till of φ of $(x$ prime) the first 2 terms give me δ till of φ of $(x$ prime). And the last 2 terms gave me for infinitesimal transformation this is nothing but $\frac{\partial\varphi}{\partial x^\mu} \delta x^\mu$. So, δ till of φ is given by this. But if I keep the transformation to first order in variation then I can rewrite this here as δ till of φ of (x) plus $\frac{\partial\varphi}{\partial x^\mu} \delta x^\mu$, because this 2 term here will be of second order quantities.

(Refer Slide Time: 36:55)

$$\tilde{\delta}\phi = \delta\phi + \frac{\partial\phi}{\partial x^\mu} \delta x^\mu$$

So, what I get here is delta till the phi is equal to delta phi plus Del phi over Del x mu delta x mu. Let we will consider the invariants reaction under this transformation and find the corresponding conserve quantities.

Thank you.
