**Exercises on Angular Momentum Operators and their algebra**

(Refer Slide Time: 00:07)

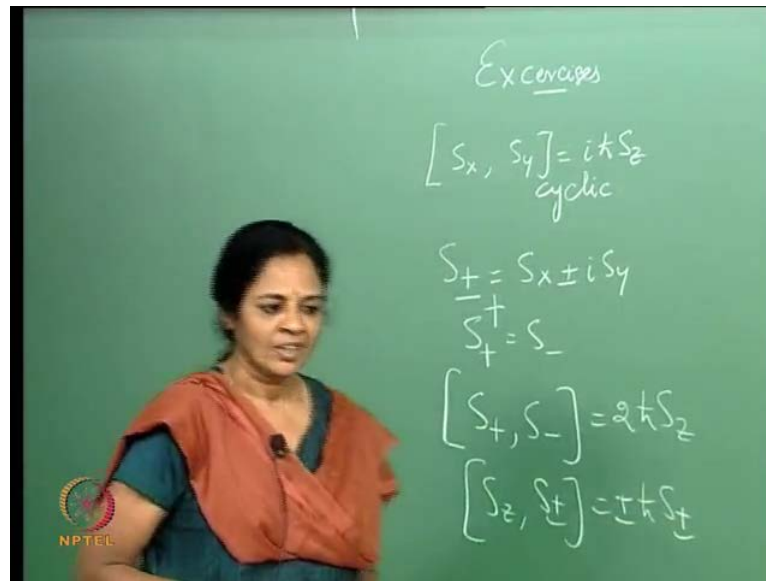

**Keywords**

- The Baker-Campbell-Hausdorff formula
- Angular momentum algebra
- Eigenvalues and Eigenvectors of angular momentum operators
- Ladder operators

In the last class, I had worked out certain exercises. Essentially pertaining to Hermitian operators, their Eigen values their Eigen vectors. And also established that, if there are 2 commuting Hermitian operators, equivalently 2 commuting Hermitian matrices, you are guaranteed that there is a complete set of common Eigen states of these 2 matrices, this can be extended, to more than 2 matrices as well.

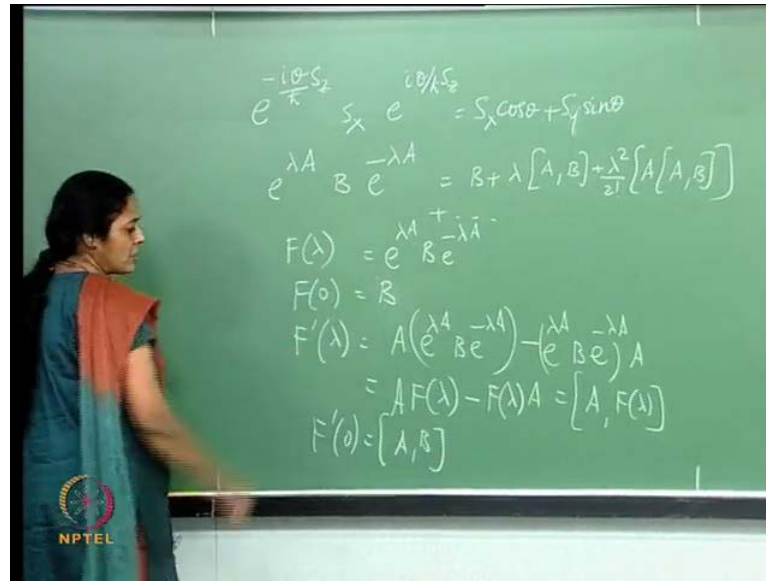

(Refer Slide Time: 00:54)

Today, I will continue to work out further exercises and today's exercises would largely be related to operators and their algebras. You are already aware of the angular momentum algebra. Where, you have the spin generators, satisfying the commutation relation. Commutator  $S_x$  with  $S_y$  is  $i\hbar$  cross  $S_z$  and that is a cyclic relation, because you could have a  $z$  here and  $x$  there and  $y$  there and so on.

You could have written the commutator this way and therefore, the algebra in the fashion, or you can define,  $S_+$  and  $S_-$  as  $S_x$  plus or minus  $iS_y$  depending upon the context and  $S_+^\dagger$  is  $S_-$ . In that case, the equivalent way of writing this algebra, is  $S_+ S_-$  is  $2\hbar$  cross  $S_z$  and  $S_z$  with  $S_+$  or minus is plus or minus  $\hbar$  cross  $S_+$  minus. So this is by way of recapitulation. We certainly use this algebra extensively, in the study of the spin doublet, the 2 level atom problem and also the 3 level atom problem.

(Refer Slide Time: 02:39)

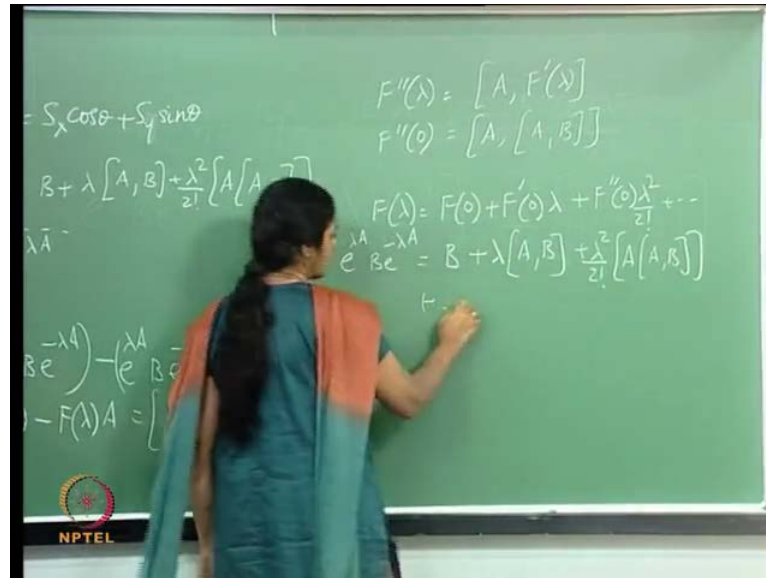

Further at one stage I derived the following relation,  $e^{-i\theta/\hbar S_z} S_x e^{i\theta/\hbar S_z} = S_x \cos\theta + S_y \sin\theta$ . Now, this is something that tells us that,  $S_x$  transforms like the  $x$  component of a vector. Similarly, if you had  $S_y$  here you will have  $-S_x \sin\theta + S_y \cos\theta$  out there, to tell you that  $S_y$  transforms like the  $y$  component of a vector and so on. I did this explicitly in one of my earlier lectures. By expanding out the exponential and then multiplying  $S_x$  across that and showing that indeed you get this as the answer.

So that  $S_x$  transforms, like the  $x$  coordinate where  $x$  prime goes to  $x \cos\theta + y \sin\theta$  under rotation by an angle  $\theta$  like that. On the other hand, later on I did put down an identity, of this form  $e^{\lambda A} B e^{-\lambda A} = B + \lambda [A, B] + \frac{\lambda^2}{2!} [A, [A, B]] + \dots$ . We use that in the context of the displacement operator and the squeezing operator as well.

At that time this identity was not proved. And I want to prove this identity now as an exercise. So I define  $F$  of  $\lambda$ , as  $e^{\lambda A} B e^{-\lambda A}$ .  $\lambda$  is the parameter, it is clear that  $F$  of  $0$  is simply  $B$ . It is assumed that  $A$  and  $B$  are Hermitian matrices that is what is of relevance to us. So,  $F'$  of  $\lambda$ , that means the differentiation with respect to  $\lambda$ , gives me  $A e^{\lambda A} B e^{-\lambda A} - e^{\lambda A} B e^{-\lambda A} A$ . I bring down the  $A$  there  $e^{\lambda A} B e^{-\lambda A} A$

but I bring down the A there. And therefore, this object is  $A F$  of  $\lambda$  minus  $F$  of  $\lambda$   $A$ . It is a commutator of  $A$  with  $F$  of  $\lambda$  it is clear that  $F'$  of  $0$  is simply the commutator of  $A$  with  $B$  because  $F$  of  $0$  is  $B$ .

(Refer Slide Time: 06:00)

Similarly, I can find out  $F$  double prime of  $\lambda$ . So,  $F$  double prime of  $\lambda$ . Clearly from here if  $F$  prime of  $\lambda$  is the commutator of  $A$  with  $F$  of  $\lambda$ ,  $F$  double prime of  $\lambda$  is the commutator of  $A$  with  $F$  prime of  $\lambda$ . And that is the same as so  $F$  double prime of  $0$  is  $A$  with  $A$  with  $B$  and so on. So, I can do the higher derivatives of  $F$ . And this is what I get for every term. Now,  $F$  of  $\lambda$  is of this structure, it is a smooth function of  $\lambda$  and therefore, can be expanded as a Taylor series in  $\lambda$ . So, I can write  $F$  of  $\lambda$  as  $F$  of  $0$  plus  $F$  prime of  $0$  times  $\lambda$ , plus  $F$  double prime of  $0$   $\lambda^2$  by  $2$  factorial and so on.

Now, if I substitute I get  $F$  of  $\lambda$  which is  $e$  to the  $\lambda A$   $B$   $e$  to the minus  $\lambda A$  is equal to  $f$  of  $0$  which is  $B$ , plus  $F$  prime of  $0$  times  $\lambda$  which is  $\lambda A$   $B$ , plus  $\lambda^2$  by  $2$  factorial  $F$  double prime of  $0$  plus so on. And that proves the point. (Refer Slide Time: 02:39) So this is the identity, this is the general identity  $e$  to the  $\lambda A$   $B$   $e$  to the minus  $\lambda A$ , is  $B$  plus,  $\lambda$  times this commutator plus  $\lambda^2$  by  $2$  factorial  $A$  with  $A$  with  $B$  commutator and so on.

So, clearly this infinite series will terminate, if one of these commutator is  $0$ . I use this specifically, in the context of squeezing in displacement operators, when we discuss the

harmonic oscillator problem and quantum optics. Now, I would like to use this identity, to establish this relation. So, let me start with  $e^{-i\theta/\hbar S_z} S_x e^{i\theta/\hbar S_z}$  to the  $i\theta/\hbar S_z$ . (Refer Slide Time: 02:39)

(Refer Slide Time: 08:44)

$$e^{-i\theta/\hbar S_z} S_x e^{i\theta/\hbar S_z} = S_x \cos\theta + S_y \sin\theta$$

$$e^{\lambda A} B e^{-\lambda A} = B + \lambda [A, B] + \frac{\lambda^2}{2!} [A, [A, B]]$$

$$\lambda = -\frac{i\theta}{\hbar}$$

$$A = S_z$$

$$B = S_x$$

$$e^{-i\theta/\hbar S_z} S_x e^{i\theta/\hbar S_z} = S_x + (-i\theta/\hbar) [S_z, S_x] + \frac{(-i\theta/\hbar)^2}{2!} [S_z, [S_z, S_x]] + \dots$$

So here  $\lambda$  is minus  $i\theta/\hbar$ ,  $A$  is  $S_z$  and  $B$  is  $S_x$ , this is what I have. If I now substitute, I have  $e^{-i\theta/\hbar S_z} S_x e^{i\theta/\hbar S_z}$  is equal to  $B$  and  $B$  is  $S_x$  plus  $\lambda$  times commutator of  $A$  with  $B$  which is minus  $i\theta/\hbar$  times the commutator of  $S_z$  with  $S_x$ , plus  $\lambda^2$  by 2 factorial, the commutator of  $A$  with the commutator of  $A$  with  $B$ , that is  $S_z$  with  $S_z S_x$  commutator plus so on.

(Refer Slide Time: 10:06)

$$\begin{aligned}
 & e^{-\frac{i\theta S_z}{\hbar}} S_x e^{\frac{i\theta S_z}{\hbar}} = S_x + \frac{\theta}{\hbar} [S_z, S_x] + \frac{\theta^2}{2! \hbar^2} [S_z, [S_z, S_x]] + \dots \\
 & = S_x + \theta S_y - \frac{\theta^2}{2!} S_x + \dots \\
 & = S_x \cos \theta + S_y \sin \theta
 \end{aligned}$$

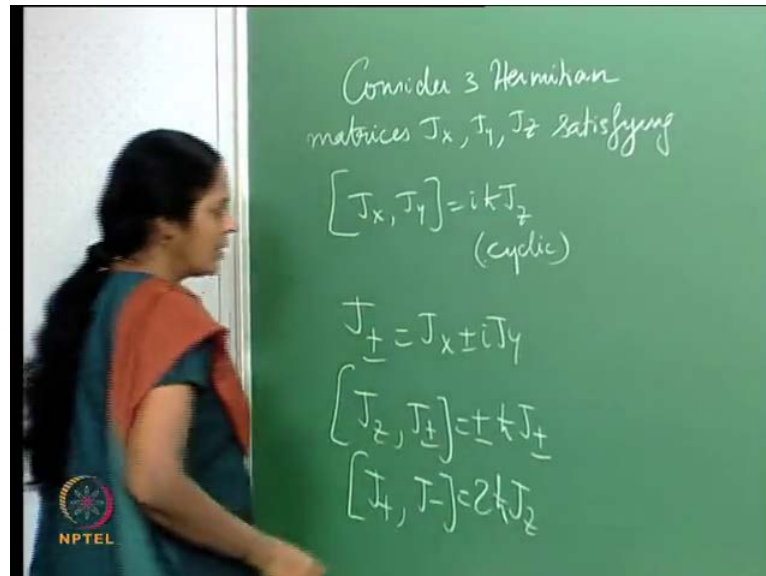

Now, again work out these commutators. (Refer Slide Time: 00:54) Simply because I know, the algebra of the spin matrices and then I have the following:  $e^{-\frac{i\theta}{\hbar} S_z} S_x e^{\frac{i\theta}{\hbar} S_z}$  is equal to  $S_x$ , (Refer Slide Time: 08:44)  $S_z$  with  $S_x$  is  $i\hbar$  cross  $S_y$ , so that gives me, plus  $\theta$  by  $\hbar$  cross  $\hbar$  cross  $S_y$ . So, that is what I get from this term. Then I have the next term, which gives me a minus  $\theta$  squared, by  $\hbar$  cross square 2 factorial. The commutator of  $S_z$  with the commutator of  $S_z$  with  $S_x$  which is  $i\hbar$  cross  $S_y$  plus so on.

And this object is  $S_x$ , plus  $\theta S_y$  minus  $\theta$  squared by 2 factorial,  $i\hbar$  cross by  $\hbar$  cross squared, that is an  $S_z$  with  $S_y$  and that is a minus  $i\hbar$  cross  $S_x$  plus so on. And that is  $S_x$  plus  $\theta S_y$  minus  $\theta$  squared by 2 factorial  $S_x$  plus so on. Now, if I work out the other terms, it will be clear that this will be  $S_x$  times  $1$  minus  $\theta$  squared by 2 factorial plus  $\theta$  to the power of four by 4 factorial and so on, which is  $S_x \cos \theta$  plus  $S_y$  the leading term is  $\theta$  when I have a  $\theta$  q by 3 factorial  $\theta$  to the 5 by 5 factorial and so on. And therefore, I get  $S_x \cos \theta$  plus  $S_y \sin \theta$ .

So this is a simple way of establishing, (Refer Slide Time: 08:44) what I set out to prove by a brute force method earlier on. I got this relation, by expanding out the exponential and doing the entire algebra. This is a neat way of doing this provided I establish this identity. Now having said that, I wish to ask some more questions on the angular

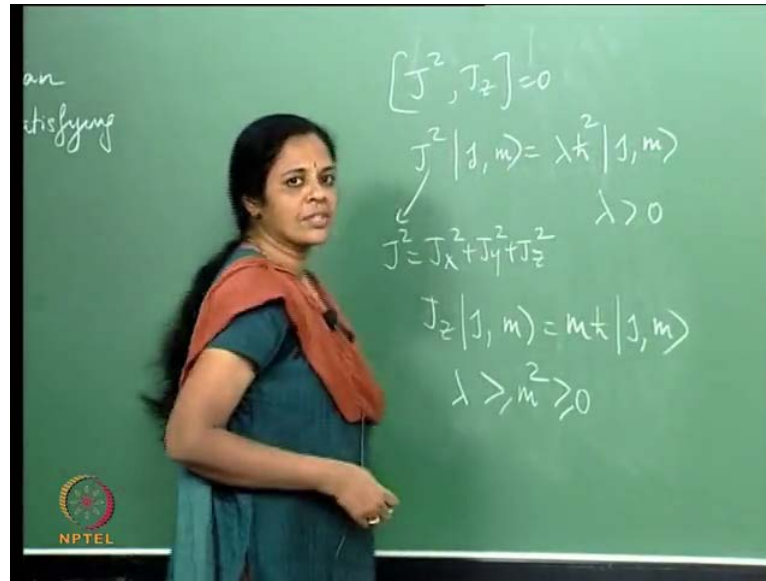

momentum algebra. We know that the orbital angular momentum components  $L_x$ ,  $L_y$  and  $L_z$  also satisfy this relation.

(Refer Slide Time: 12:49)

And therefore, in general consider, 3 Hermitian matrices,  $J_x$ ,  $J_y$ ,  $J_z$  satisfying the Lie algebra  $J_x J_y$  commutator is  $i\hbar$  cross  $J_z$  cyclic relation. Define  $J_+$  and  $J_-$  as  $J_x \pm iJ_y$ , and then surely  $J_z J_+ = J_+ J_z + \hbar J_+$  and  $J_z J_- = J_- J_z - \hbar J_-$ , and  $J_+ J_- = J_- J_+ + 2\hbar J_z$ . Now  $J$  could represent the spin matrices,  $J_x$  could be  $S_x$ ,  $J_y$  could be  $S_y$  and  $J_z$  could be  $S_z$ , or if we are discussing orbital angular momentum,  $J_x$  would be denoted by  $L_x$ ,  $J_y$  by  $L_y$ ,  $J_z$  by  $L_z$  where  $\mathbf{l}$  itself is our cross product. The algebra is the same the situation is different. In the one case we are dealing with an intrinsic property called spin. The other case we are dealing with something in physical space called orbital angular momentum.

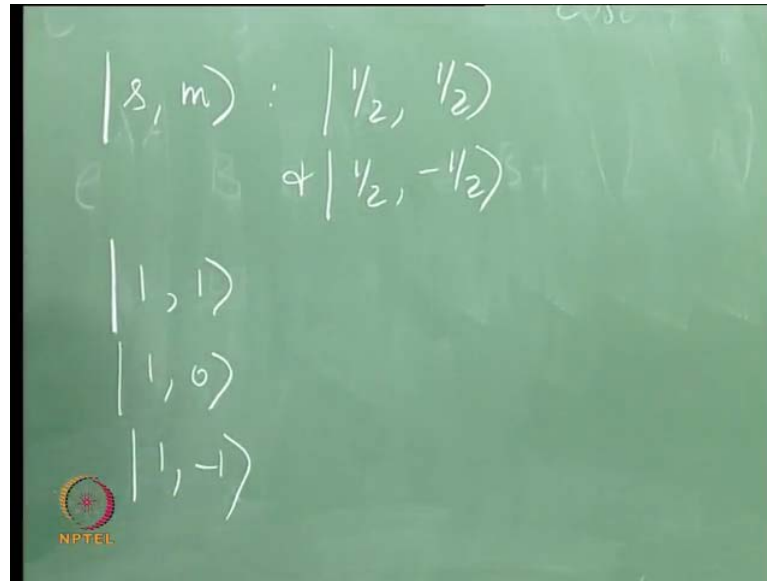

(Refer Slide Time: 14:30)

The question that I wish to ask is the following. I know therefore, that  $J^2$  and  $J_z$  commute with each other. I have already established therefore, that there is a complete set of common Eigen states of  $J^2$  and  $J_z$ . Let me denote, the Eigen states by  $J, m$ . In the case of spin this would be given by the label  $s$  and  $m$  would be the 3rd component of spin the Eigen value of  $S_z$ . In the case of orbital angular momentum, this would be replaced by  $l$  and that would continue to be  $m$ , where now  $m$  denotes the Eigen value of  $L_z$ .

So  $J^2$   $J, m$  I know that there is an Eigen state  $J, m$  of  $J^2$ . And since  $J^2$  is a positive definite operator, recall that  $J^2$  is  $J_x^2 + J_y^2 + J_z^2$ . I can well write this Eigen value this  $\lambda h^2$ ,  $\lambda$  is to be determined and it is clear that,  $\lambda$  is greater than zero. Now  $J_z$   $J, m$  I know is  $m h$  cross ket  $J, m$   $m^2$  has to be determined given  $\lambda$ . One thing is clear that since  $J^2$  is  $J_z^2$  plus some positive quantities,  $\lambda$  is greater than or equal to  $m^2$  and  $m^2$  itself, by its very nature is greater than 0, greater than or equal to 0. So this is evident, we now need to find out the values, the set of values that  $\lambda$  can take and the set of values, that  $m$  can take. You will recall that when we did the 2 level atom problem. We had two Eigen states of spin. I label them ket  $s, m$  and ket  $s, \text{minus } m$ , in the following sense.

(Refer Slide Time: 16:57)

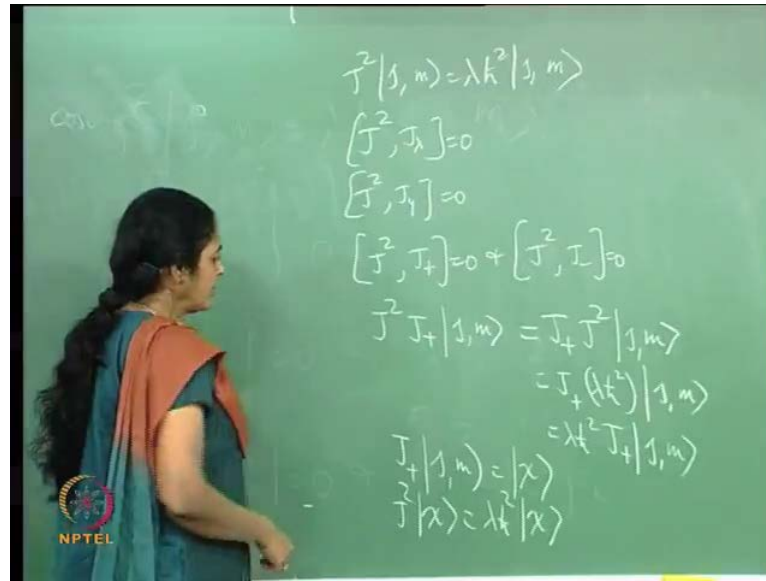

The image shows a green chalkboard with handwritten quantum state notations. At the top, it says  $|s, m\rangle : |1/2, 1/2\rangle$  and  $|1/2, -1/2\rangle$ . Below this, it lists three states:  $|1, 1\rangle$ ,  $|1, 0\rangle$ , and  $|1, -1\rangle$ . In the bottom left corner, there is a small circular logo with a star and the text "NPTEL" below it.

In the case of the spin doublet, we had half, half and half, minus half, so there was an  $s$ ,  $m$  the same  $s$  with a minus  $m$ . This is what we had as the Eigen basis the spin Eigen basis, in the case of the spin doublet. And we simply noted the fact that  $m$  took values minus  $s$  to plus  $s$  in steps of 1. Similarly, when we did the 3 level atom problem and we had the same algebra as the angular momentum algebra or the spin algebra. We had 3 basis states and the values were 1, 1, 0 and 1, minus 1.

So when  $s$  was 1, again we realize that  $m$  took values minus  $s$  to plus  $s$ , in steps of 1. We would like to see if in general, this can be established. (Refer Slide Time: 14:30) In other words we want to find the value, the set of values that  $\lambda$  can take and the set of values that  $m$  can take. It is clear, that  $\lambda$  is simply a function of  $J$ ;  $m$  has to be determined in terms of  $\lambda$ .

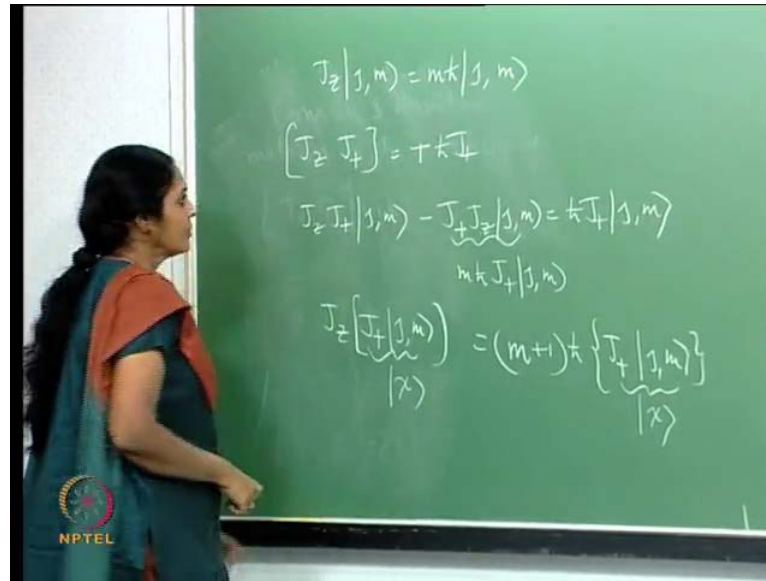

(Refer Slide Time: 18:25)

We proceed to do this as follows. Let us start with the fact that  $J^2$  commutes with  $J_x$  and  $J^2$  commutes with  $J_y$ . Therefore,  $J^2$  commutes with  $J_+$  and  $J^2$  commutes with  $J_-$ . Recall that  $J_+$  is  $J_x + i J_y$  and  $J_-$  is  $J_x - i J_y$ . I therefore have,  $J^2 J_+$  this operator acting on the state  $|j, m\rangle$  to be equal to  $J_+ J^2$  acting on the state  $|j, m\rangle$ . I know that this object is  $J_+$  times the number  $\lambda h^2$  acting on the state  $|j, m\rangle$ . And since that is a number I can pull that out and I have  $J_+ |j, m\rangle$ . Call the state  $J_+ |j, m\rangle$ , as some ket  $|\chi\rangle$  it is now clear, that  $J^2 |\chi\rangle = \lambda h^2 |\chi\rangle$ .

In other words we are saying that  $J_+$  acting on the state  $|j, m\rangle$ , takes it to another state which I have represented by ket  $|\chi\rangle$  symbolically. That state is also an Eigen state of  $J^2$  with the same Eigen value  $\lambda h^2$ , recall that  $J^2$  acting on the state  $|j, m\rangle$ , gave me Eigen value  $\lambda h^2$ . Now, it seems that  $J_+ |j, m\rangle$  this state, is also an Eigen state of  $J^2$  with the same Eigen value  $\lambda h^2$ . And therefore, when  $J_+$  acts on the state  $|j, m\rangle$  the ket  $|j, m\rangle$ , it does not change the Eigen value corresponding to  $J^2$ .

(Refer Slide Time: 20:42)

On the other hand, consider the commutator  $J_z$  with  $J_+$ . Now,  $J_z$  with  $J_+$  is plus  $\hbar$  cross  $J_+$ , look at the state  $J_z J_+ |j, m\rangle$  from this algebra I have that  $J_z J_+ |j, m\rangle - J_+ J_z |j, m\rangle = \hbar J_+ |j, m\rangle$ . Well certainly this object  $J_z$  acting on  $J_+ |j, m\rangle$  is  $m \hbar$  cross, which is a number and therefore, I can pull that out and write the 2nd term in this manner. Therefore, I have  $J_z J_+ |j, m\rangle = J_+ J_z |j, m\rangle + \hbar J_+ |j, m\rangle$ ,  $J_z$  operating on this state which I labeled as  $|\chi\rangle$  symbolically.

This is equal to  $m \hbar$  cross  $J_+ |j, m\rangle$  this was  $|\chi\rangle$ . I have therefore, established that  $J_+$ , acting on the state  $|j, m\rangle$  the resultant state here is an Eigen state of  $J_z$ . But, with an Eigen value not  $m \hbar$  cross but  $(m+1) \hbar$  cross. Recall, that  $J_z$  acting on  $|j, m\rangle$  was  $m \hbar$  cross  $|j, m\rangle$ . It is therefore, clear that the operation of  $J_+$  on the state  $|j, m\rangle$  is as follows. It is not seem to change the  $J$  value but it does change  $m$  to  $m+1$ .

(Refer Slide Time: 22:58)

$$[J^2, J_-] = 0$$

$$J^2 J_- |j, m\rangle = J_- J^2 |j, m\rangle$$

$$J^2 \{J_- |j, m\rangle\} = \lambda h^2 \{J_- |j, m\rangle\}$$

$$[J_z, J_-] = -\hbar J_-$$

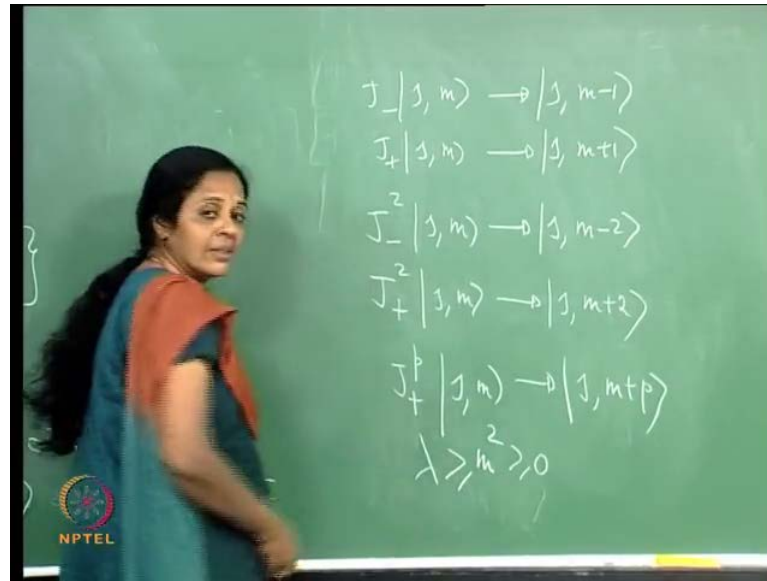

$$J_z J_- |j, m\rangle - J_- J_z |j, m\rangle = -\hbar J_- |j, m\rangle$$

$J_z |j, m\rangle = \lambda \hbar |j, m\rangle$

Now, let us look at what  $J_-$  does to the state  $|j, m\rangle$ . I repeat this argument. I start off with the fact, that  $J^2 J_-$  is equal to 0. And therefore,  $J^2 J_- |j, m\rangle$  is equal to  $J_- J^2 |j, m\rangle$ . But, this is simply  $\lambda h^2 J_- |j, m\rangle$ . Hence, I see that the state  $J_- |j, m\rangle$  is an Eigen state of  $J^2$ , with Eigen value  $\lambda h^2$ . In other words, I have shown that  $J_-$  acts on the state  $|j, m\rangle$  without changing the Eigen value, that seems to be the same.

And since  $\lambda$  is a function of  $J$  it looks like  $J$  is not changing when  $J_-$  acts on  $|j, m\rangle$ . So whatever I said about  $J_+$  acting on  $|j, m\rangle$  also holds for  $J_-$  acting on  $|j, m\rangle$  in the sense that the  $J$  value does not change. On the other hand I know that the commutator,  $J_z$  with  $J_-$  is  $-\hbar J_-$  and therefore, if I acted this commutator on the state  $|j, m\rangle$  I get the following.

(Refer Slide Time: 25:01)

I know that this is  $m$  h cross  $J, m$ . It is therefore clear that, when  $J$  minus acts on the state  $J, m$  it reduces the  $m$  value by 1. Takes it to the state  $J, m$  minus 1 and  $J$  minus acts on  $J, m$ , and when  $J$  plus acts on  $J, m$  it takes it to a state where the  $m$  value increases by 1. So in this sense, that we say that  $J$  plus and  $J$  minus are the lowering and the raising operators respectively. They leave  $J$  untouched, but change the third component value  $m$ .  $J$  minus decreases it by 1 and  $J$  plus increases it by 1, if it acts once.

It is clear that if  $J$  minus acts twice on  $J, m$ , this means it acts twice on  $J, m$  it takes it to the state  $J, m$  minus 2 and if  $J$  plus acts twice takes it to the state  $J, m$  plus 2. In this sense they are raising and lowering operators or ladder operators. However, this cannot go on indefinitely because if  $J$  plus acts  $p$  times say on  $J, m$  from whatever I have shown you till now, this takes it to a state  $J, m$  plus  $p$  but I have the constraint, that  $\lambda$  corresponding to the Eigen value of  $J$  squared is greater than or equal to  $m$  squared and that of course, is greater than or equal to 0.

We began there so you see this cannot be increasing indefinitely, because there should come a stage where if I denote  $m$  plus  $p$  by  $m$  prime there should come a stage corresponding to some  $p$ , where  $m$  prime squared cannot be greater than  $\lambda$ . So there must be an upper value, beyond which  $J$  plus cannot increase the 3rd component value by 1.

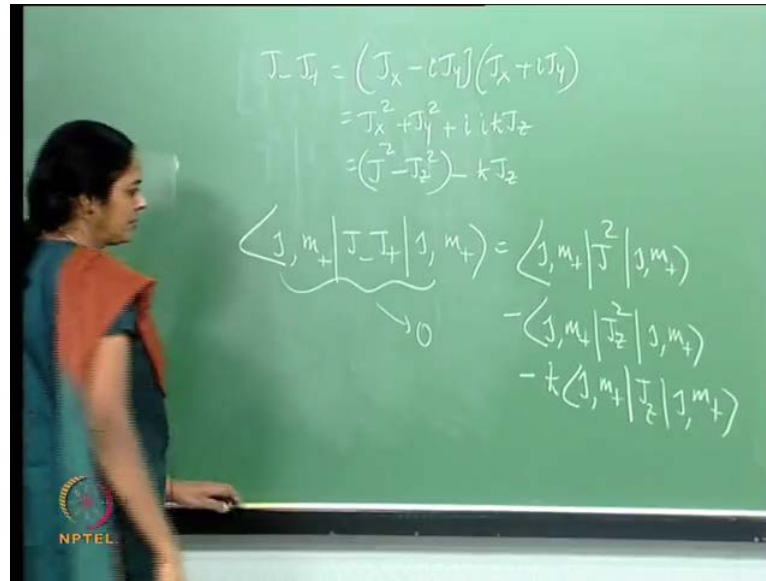

(Refer Slide Time: 27:37)

In other words I have the following condition now, I realize the following that there is an upper bound of  $m$  which I will call  $m$  plus such that when  $J$  plus acts on the state  $J, m$  plus, it gives me 0 because otherwise  $m$  plus squared could be greater than  $\lambda$  and  $\lambda$  is a function of  $J$ . Similarly, I know that there must be a lower bound for the same reasons, there is an  $m$  minus every time  $J$  minus acts on  $m$  it reduces the value of  $m$  by one but then there must be an  $m$  minus, which fixes the lower bound because  $J$  minus acting on  $J, m$  minus must be equal to 0.

Simply because (Refer Slide Time: 25:01) this constraint has to be satisfied. Look at the first relation I therefore, have  $J m$  plus  $J$  plus dagger which is  $J$  minus is equal to 0, consider the object  $J m$  plus  $J$  minus  $J$  plus  $J m$  plus, it is clear that this is 0 because  $J$  plus acting on  $J m$  plus is 0 similarly, the  $J$  minus acting on this side  $J m$  plus is 0. but, I can write  $J$  minus  $J$  plus in terms of  $J$  squared and  $J z$  in the following manner.

(Refer Slide Time: 29:19)

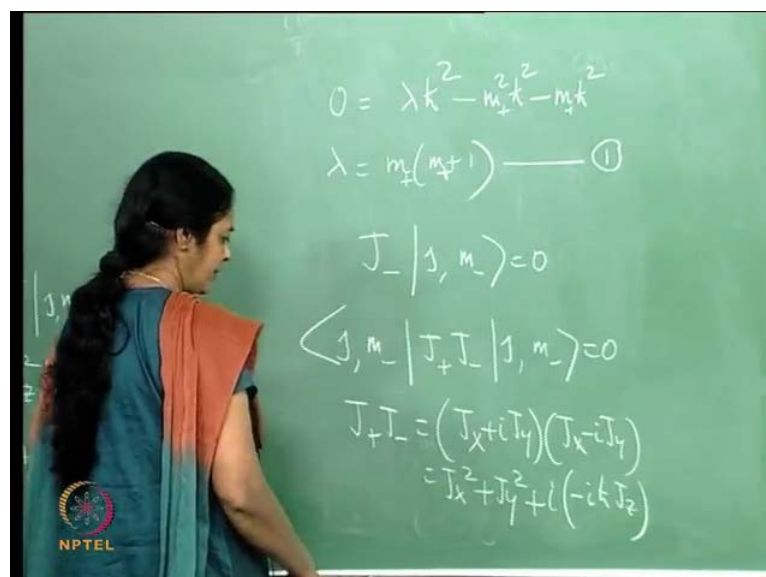

$$\begin{aligned}
 J_- J_+ &= (J_x - iJ_y)(J_x + iJ_y) \\
 &= J_x^2 + J_y^2 + i[J_x, J_y] \\
 &= (J^2 - J_z^2) - \hbar J_z
 \end{aligned}$$

$$\begin{aligned}
 \langle j, m_+ | J_- J_+ | j, m_+ \rangle &= \langle j, m_+ | J^2 | j, m_+ \rangle \\
 &\quad - \hbar \langle j, m_+ | J_z | j, m_+ \rangle \\
 &\quad - \hbar \langle j, m_+ | J_z | j, m_+ \rangle
 \end{aligned}$$

$J_- J_+$  when written in terms of  $J_x$  and  $J_y$ , is  $J_x^2 - J_y^2 + i[J_x, J_y]$  in this object is  $J_x^2 + J_y^2 + i$  commutator of  $J_x$  with  $J_y$  which is  $i\hbar J_z$ . But, that the same as  $J^2 - J_z^2 - \hbar J_z$ . I therefore, find that in there and I have,  $J_- J_+$  sandwiched between these states is the same as  $J^2 - J_z^2 - \hbar J_z$  sandwiched between these states. And this object I know is 0. That these  $|j, m_+ \rangle$  is an Eigen state of  $J^2$ ,  $J_z^2$  and  $J_z$ . So I might as well pull out the Eigen values.

(Refer Slide Time: 31:03)

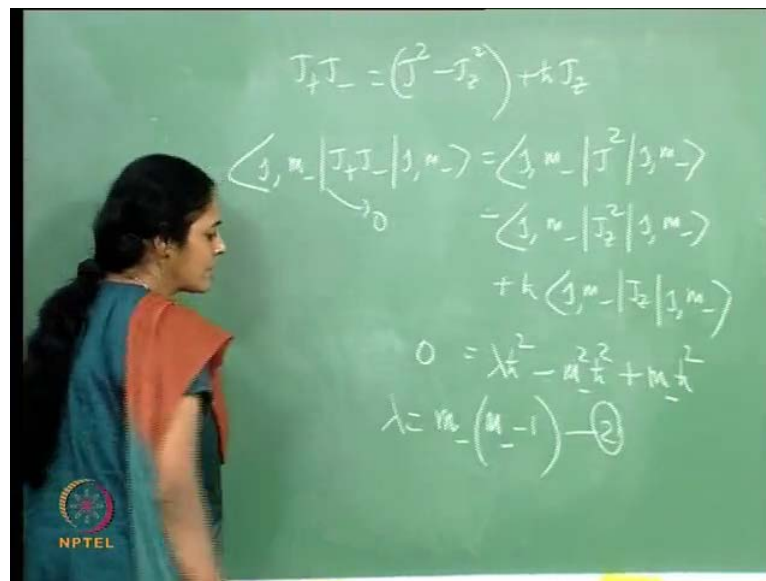

$$\begin{aligned}
 0 &= \lambda \hbar^2 - m_+^2 \hbar^2 - m_+^2 \hbar^2 \\
 \lambda &= m_+(m_+ + 1) \quad \text{--- ①}
 \end{aligned}$$

$$\begin{aligned}
 J_- |j, m_- \rangle &= 0 \\
 \langle j, m_- | J_+ J_- | j, m_- \rangle &= 0 \\
 J_+ J_- &= (J_x + iJ_y)(J_x - iJ_y) \\
 &= J_x^2 + J_y^2 + i[J_y, J_x]
 \end{aligned}$$

And then I have the following I have 0 is equal to, (Refer Slide Time: 29:19) the first term gives me a  $\lambda \hbar^2$  cross squared these are normalized states. So the inner product of  $J_+ J_- |j, m\rangle$  with  $|j, m\rangle$  is 1 and therefore, I just get  $\lambda \hbar^2$  cross squared from the first term, minus  $m^2 \hbar^2$  cross squared from the second term, (Refer Slide Time: 29:19) minus  $m \hbar^2$  cross squared from the third term, which tells me that  $\lambda$  is equal to  $m(m+1)$  except that in all these cases it is  $m+1$ , it is  $m+1$  times  $m+1$ .

So, this is the first relation I get which relates  $\lambda$  to the upper bound on  $m$  which I have denoted by  $m_+$ , I can repeat this calculation starting with the fact, that  $J_-$  acting on the state  $|j, m_+ \rangle$  is 0. Therefore, I have this object to be 0 but once more I can write this in terms of  $J^2$ ,  $J_z^2$  and  $J_z$  because  $J_+ J_-$  product is  $J_x^2 + J_y^2 + i[J_y, J_x]$ , that is  $J_x^2 + J_y^2 + i$  commutator of  $J_y$  with  $J_x$ , the commutator of  $J_y$  with  $J_x$  is  $-i\hbar J_z$ , this therefore, tells me the following.

(Refer Slide Time: 33:04)

$$J_+ J_- = (J^2 - J_z^2) + \hbar J_z$$

$$\langle j, m_+ | J_+ J_- | j, m_+ \rangle = \langle j, m_+ | J^2 | j, m_+ \rangle - \langle j, m_+ | J_z^2 | j, m_+ \rangle + \hbar \langle j, m_+ | J_z | j, m_+ \rangle$$

$$0 = \lambda \hbar^2 - m_+^2 \hbar^2 + m_+ \hbar^2$$

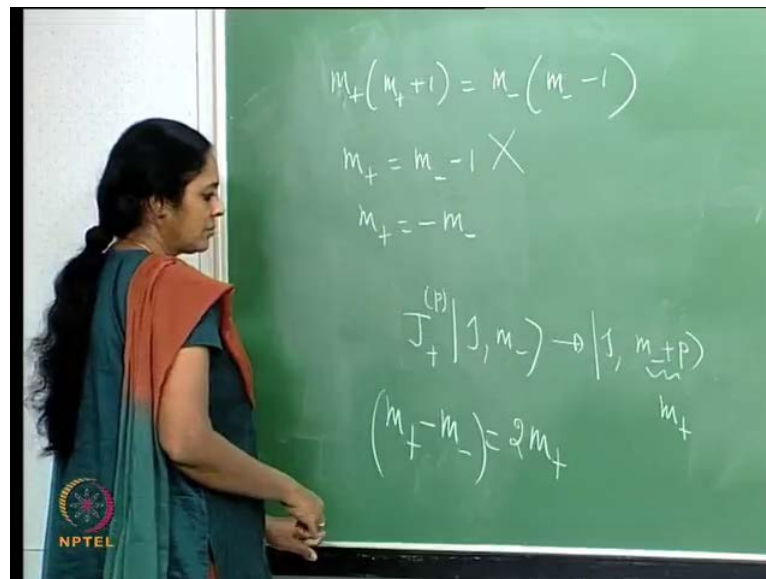

$$\lambda = m_+(m_+ + 1) \quad (2)$$

I have  $J_+ J_- = J^2 - J_z^2 + \hbar J_z$  (Refer Slide Time: 31:03) because I have written  $J_x^2 + J_y^2$  in that fashion, plus  $\hbar J_z$ , taking the expectation value in this manner. This object is 0 remember is simply the following, as before I have this minus this object plus  $\hbar J_z$ . Well that gives me, a  $J^2$  a  $\lambda \hbar^2$  cross squared it pulls out  $\lambda \hbar^2$  cross squared this pulls out plus

$m^2 \hbar^2$  except that  $m$  is now  $m_-$ , comes with a negative sign because of the negative sign here plus  $m_- \hbar^2$ . Since, this object is equal to 0.

I have  $\lambda$  is equal to  $m_- (m_- - 1)$  and that is a second relation that I have. (Refer Slide Time: 31:03) So I have two descriptions of  $\lambda$   $\lambda = m_+ (m_+ + 1)$  is also equal to  $m_- (m_- - 1)$ . I emphasize that  $m_+$  is the higher bound on the value that  $m$  can take for a given  $J$  and  $m_-$  is the lowest value that  $m$  can take for the same value of  $J$ . (Refer Slide Time: 25:01) Since these two are equal I have the following.

(Refer Slide Time: 35:24)

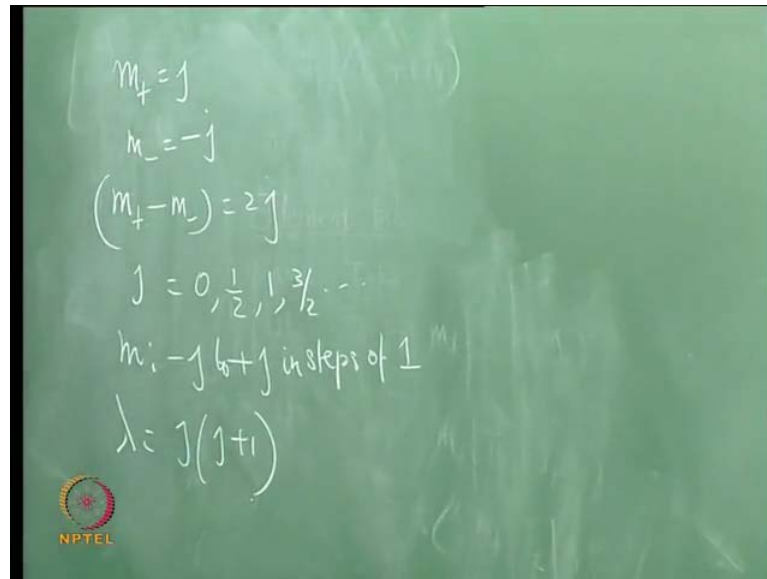

I have  $m_+ (m_+ + 1) = m_- (m_- - 1)$ . Well this tells me the following, I can have one of two solutions. I can have  $m_+ = m_- - 1$ , certainly that is satisfied or  $m_+ = -m_-$  this is another possibility. We need to understand that this is not possible, this is not possible because if I had started with the state  $|J, m_->$  and repeatedly applied,  $J_+$  on it to the power of  $p$  perhaps I would have landed in a state  $|J, m_- + p>$  and  $m_+$  was the highest value that it could have taken.

As a result of which  $m_+$  is greater than  $m_-$  the difference between  $m_+$  and  $m_-$  has to be an integer, because every time  $J_+$  acts on this state it increases the  $m$  value by 1. And therefore, I know that the difference  $m_+ - m_-$  is an

integer. I also know that  $m_+$  is the upper bound and  $m_-$  is the lower bound on  $m$  and therefore, this relation is not true whereas, this is more acceptable. And therefore, if  $m_+$  is equal to  $m_-$  then  $m_+ - m_- = 2m_+$ . The solution is this, since  $\lambda$  is simply a function of  $J$ . (Refer Slide Time: 35:24) I now have  $m_+ - m_- = 2m_+$

(Refer Slide Time: 37:38)

$$m_+ = J$$

$$m_- = -J$$

$$(m_+ - m_-) = 2J$$

$$J = 0, \frac{1}{2}, 1, \frac{3}{2}, \dots$$

$$m: -J \text{ to } J \text{ in steps of } 1$$

$$\lambda = J(J+1)$$

And  $m_+$  is  $J$  and therefore,  $m_-$  is  $-J$ . And therefore,  $m_+ - m_-$  is  $2J$ . But, this is an integer. Therefore  $J$  takes values  $0, \frac{1}{2}, 1, \frac{3}{2}, 2$  and so on. If this is  $0$  of course, it is  $0$  if this  $1$  it is half, if it is  $2$  it is  $1$  and so on. And  $m$  can take values  $-J$  to  $J$  in steps of  $1$  and  $\lambda$  itself is therefore,  $J(J+1)$  (Refer Slide Time: 35:24) it is  $J(J+1)$ . So what we have established is the following, simply on the basis of the  $su(2)$  algebra

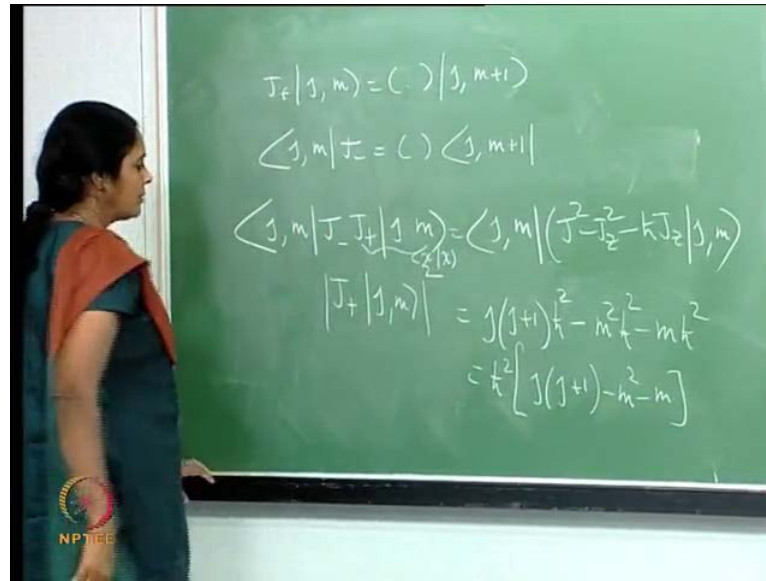

(Refer Slide Time: 38:47)

$$J_z |j, m\rangle = m\hbar |j, m\rangle$$
$$j = 0, \frac{1}{2}, 1, \frac{3}{2}, \dots$$
$$j: m: -j \text{ to } +j \text{ in steps of } 1$$
$$(2j+1) \text{ values for a given } j$$
$$\text{ranging from } -j \text{ to } +j \text{ in steps of } 1$$

we have established that  $J^2$  acting on  $|j, m\rangle$  is  $j(j+1)\hbar^2 |j, m\rangle$ ,  $J_z$  acting on  $|j, m\rangle$  is  $m\hbar |j, m\rangle$ .  $j$  takes values  $0, \frac{1}{2}, 1, \frac{3}{2}, 2, \dots$  and so on. It takes integer or half integer values, for a given value of  $j$ ,  $m$  takes values  $-j$  to  $+j$  in steps of one. You will recall that this is  $m$  plus and that was  $m$  minus the upper and lower bounds on  $m$ . And every time  $J_-$  acted on a state it reduced the value of  $m$  by 1 if  $J_+$  acted on the state it increased the value by 1. And therefore,  $m$  takes  $2j+1$  values over the range  $-j$  to  $+j$ , for a given  $j$  ranging from  $-j$  to  $+j$  in steps of 1.

And indeed this is what we had verified, when we did the spin doublet problem equivalently the two level atom problem. When we had the two basis states  $\frac{1}{2}, \frac{1}{2}$  if  $j$  was  $\frac{1}{2}$  call it  $s$  then because it was spin. The second entry was  $m$ , so we had two states  $\frac{1}{2}, \frac{1}{2}$  and  $\frac{1}{2}, -\frac{1}{2}$ . So  $m$  took values  $-\frac{1}{2}$  to  $+\frac{1}{2}$  in steps of 1. When we did the three level atom problem, we had the states  $1, 1, 0$  and  $1, -1$ , once more for given value of  $j$  in this case it was 1,  $m$  took values  $-1, 0$  and  $+1$ , ranging from  $-j$  to  $+j$  in steps of 1. We can now proceed, and find out what exactly is the action of  $J_+$  on  $|j, m\rangle$ . We have realized that  $J_+$  is raising operator it takes  $|j, m\rangle$  to  $|j, m+1\rangle$  but what are the coefficients what is the coefficient outside.

(Refer Slide Time: 41:25)

$$J_- |j, m\rangle = C_- |j, m-1\rangle$$

$$\langle j, m | J_- = C_- \langle j, m+1 |$$

$$\langle j, m | J_- J_+ | j, m \rangle = \langle j, m | (J^2 - J_z^2 - \hbar J_z) | j, m \rangle$$

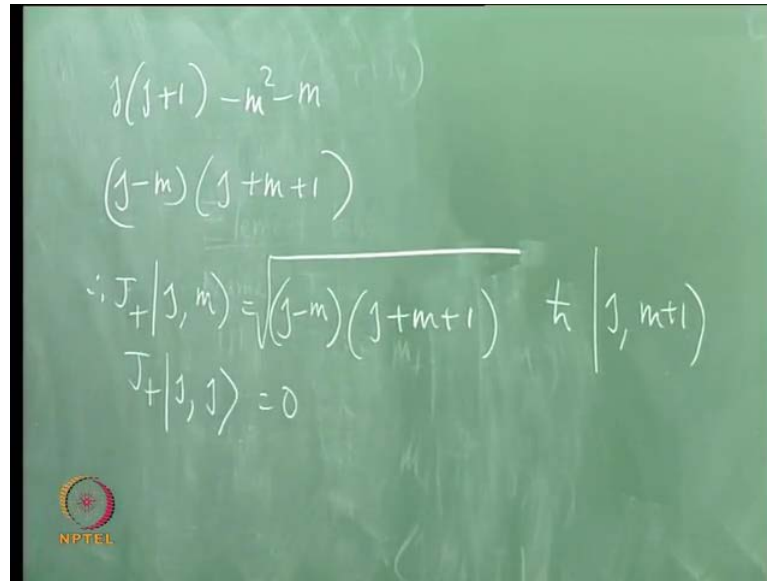

$$|C_-|^2 |j, m\rangle = j(j+1)\hbar^2 - m^2\hbar^2 - m\hbar^2$$

$$= \hbar^2 [j(j+1) - m^2 - m]$$

So for doing that we need to find out this object, we need to find out this object. What is it that multiplies this ket  $J, m$  plus 1 this can be handled in the following fashion; this is what I have when I take the Hermitian conjugate. So I consider the object  $J, m, J$  minus  $J$  plus  $J, m$ . It is pretty clear that  $J$  plus will increase the  $m$  value to  $m$  plus 1. And therefore, this would go to a state  $J, m$  plus 1. But,  $J$  minus will act on that state and decrease the  $m$  value by 1 again, bringing it back to  $J, m$  and then the orthogonality relation, the fact that  $J, m$  inner product with  $J, m$  is 1, that will give us a number.

That is precisely what is happening, and as we did earlier we can substitute for  $J$  minus  $J$  plus. So  $J$  minus  $J$  plus was  $J$  squared minus  $J_z$  squared minus  $\hbar$  cross  $J_z$  this is what I have. It's also clear that this object can be written as  $J$  plus  $J, m$  squared, not squared because  $J$  plus  $J, m$  is like some ket  $\chi$  this is like the bra. And therefore, this is like mode square of that object. The coefficients are in general the coefficients here are in general taken to be real and therefore, if I evaluate the number here that will be the square of the coefficient arrival need here. So, this object is  $J$  into  $J$  plus 1  $\hbar$  cross squared minus  $m$  squared  $\hbar$  cross squared minus  $m$   $\hbar$  cross squared. This is the same as  $\hbar$  cross squared  $J$  into  $J$  plus 1 minus  $m$  squared minus  $m$ ; this is the square of the number that comes here.

(Refer Slide Time: 44:15)

The image shows a green chalkboard with handwritten mathematical expressions. At the top, the expression  $J(J+1) - m^2 - m$  is written. Below it, the expression  $(J-m)(J+m+1)$  is written. A horizontal line is drawn under the expression  $(J-m)(J+m+1)$ . Below the line, the expression  $\therefore J_+ |J, m\rangle = \sqrt{(J-m)(J+m+1)} \hbar |J, m+1\rangle$  is written. Below this, the expression  $J_+ |J, J\rangle = 0$  is written. In the bottom left corner, there is a small logo with the text "NPTEL" below it.

And therefore, the number that comes here can be easily evaluated. I would like to write  $J$  into  $J$  plus 1 minus  $m$  squared minus  $m$  as  $J$  minus  $m$  into  $J$  plus  $m$  plus 1 that is a way of writing it. And therefore,  $J$  plus acting on  $J$   $m$  is the square root of  $J$  minus  $m$  into  $J$  plus  $m$  plus 1, there is an  $\hbar$  cross  $J$   $m$  plus 1 the  $\hbar$  cross was because I needed to take the square root of this object and therefore, I got the  $\hbar$  cross. The  $\hbar$  cross is outside the square root. It is clear therefore, that when  $J$  plus acts on the state  $J, J$  which is the maximum value that  $m$  can take that gives me 0, which is consistent with what I wanted that  $J, J$  was the upper most state that I can have and  $J$  plus cannot raise the  $m$  value beyond that.

(Refer Slide Time: 45:38)

$$J_- |j, m\rangle = ( ) |j, m-1\rangle$$

$$\langle j, m | J_+ J_- |j, m\rangle = \langle j, m | J^2 - J_z^2 + \hbar J_z |j, m\rangle$$

$$= [j(j+1) - m^2 + m] \hbar^2$$

$$\left( \sqrt{j+m} \sqrt{j-m+1} \right)^2 \hbar^2$$

Similarly, I can find out the effect of J minus acting on J, m. Quite apart from taking this state to the state J, m minus 1 what is it that multiplies it what is the constant that multiplies it. Some number so, I need to find this number as before I try to find this, that is going to be J, m J plus J minus is J squared minus J z squared plus h cross J z J, m as before, I have this to be J into J plus 1 minus m squared plus m h cross squared. And this can be written as root of J plus m into J minus m plus 1 it is simply a way of writing it, the whole squared, from which it is clear.

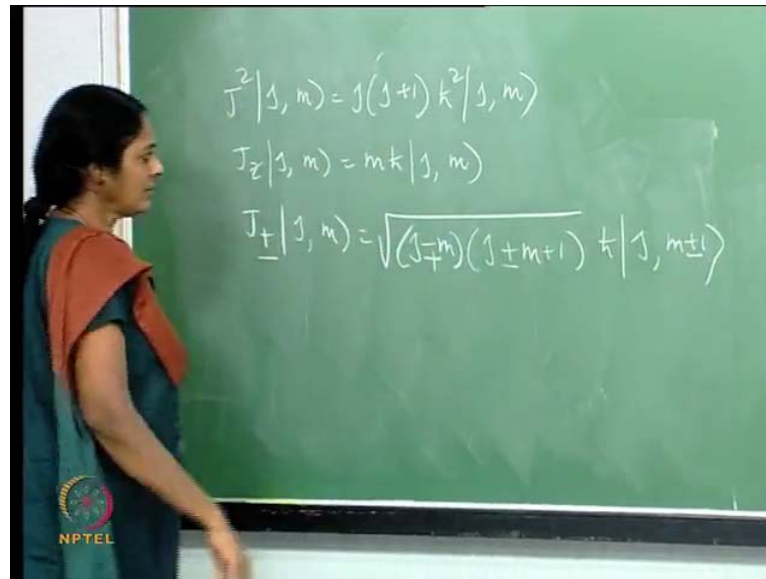

(Refer Slide Time: 47:00)

$$J_- |j, m\rangle = \sqrt{j+m} \sqrt{j-m+1} \hbar |j, m-1\rangle$$

$$J_- |j, -j\rangle = 0$$

That  $J_-$  acting on the state  $J, m$  gives me root of  $J$  plus  $m$  into  $J$  minus  $m$  plus 1  $\hbar$  cross  $J, m$  minus 1. Once more it is clear, that when  $J_-$  acts on the state  $J, m$  minus  $J$ , that is the lowest value that  $m$  can take I refer to this as  $m$  subscript minus earlier on when I did the derivation, this object is automatically 0 because  $J$  minus  $J$  is 0 and that is what I want. There is a lower bound and  $J_-$  acting on that state gives me 0.

(Refer Slide Time: 47:57)

To summarize therefore, I have gotten for you the angular momentum algebra. And the manner in which these states act the operators acts on the states, I have  $J^2$  acting on  $J, m$  is  $J$  into  $J$  plus 1  $\hbar$  cross squared  $J, m$   $J_z$  acting on the state  $J, m$  is  $m \hbar$  cross  $J, m$ ,  $m$  taking  $2J$  plus 1 values ranging from minus  $J$  to plus  $J$  in steps of 1. I have  $J_+$   $J, m$  is root of  $J$  minus  $m$  into  $J$  plus  $m$  plus 1  $\hbar$  cross  $J, m$  plus 1 and  $J_-$  acting on  $J, m$  gives me this. So this is the manner in which, the angular momentum operators act on the basis states  $J, m$ , what I said holds for spin matrices where  $J$  is replaced simply by the label  $s$  and orbital angular momentum, where  $J_x, J_y, J_z$  are denoted in this context as  $l_x, l_y$  and  $l_z$ , being  $x, y$  and  $z$  components of the orbital angular momentum operator.
