Lecture - 29
The Wavefunction: Its Single-Valuedness and its Phase

(Refer Slide Time: 00:07)

Till now, we have been looking at one dimensional problem. We looked at the linear harmonic oscillator, also at the square well potential. Now, in all those cases we could identify a length factor, an object of the dimensions of length which I could make with the parameters available in the problem.

(Refer Slide Time: 00:36)

Now, you will recall that in the case of the linear harmonic oscillator we had root of h cross by m omega and that gave us the dimensions of length. Similarly, in the case of the square well potential, the potential itself was nonzero from minus a to a . So, x taking values minus a to a , V was minus V_0 . Therefore, I had a length scale which was naturally there in the problem and that is needed in order to have a bound state. The surprising thing about the quantum mechanics as I have also reiterated in the past, is that there are classically forbidden regions which are accessible to the quantum state. For instance, in the case of the harmonic oscillator, if you had plotted V of x versus x , that was a parabola going all the way up. And a classical particle would be confined to this region.

In fact, for a given value of energy the classical oscillator goes there. That is the turning point turns back, comes here, that is another turning point and that is the oscillation like this. But, as you know even in the ground state of the harmonic oscillator, the wavefunction is a Gaussian and therefore, the Gaussian dies down only at large x . So, the probability of seeing the object away or outside of the potential is also nonzero and therefore, classically forbidden regions are accessible. Similarly in the case of the square well, the particle which was confined to the square well could well have a nonzero probability of being outside the square well. So, this was one of the surprises from the quantum version of these problems.

Today I would like to look at three dimensional problems. The simple example that we can talk about is the case, where there is a central potential. So, if the potential V is simply a function of r and I have used spherical polar coordinates. An example could well be the coulomb problem, where the potential is minus $z e$ square by r . So, we look at situations like this where we will be dealing with central potentials, a three dimensional problem. For instance, the hydrogen atom where there is proton in the nucleus and an electron outside of the nucleus. So, such problems would show a certain amount of symmetry, because if the potential is central then you know that orbital angular momentum is conserved.

L^2 , the angular momentum operator square, is the generator of space rotations and therefore, I would expect that if L^2 the operator were written in spherical polar coordinates it would merely be a function of θ and ϕ . We can write L^2 in terms of θ and ϕ and not r , as a differential operator involving $\partial/\partial\theta$ and $\partial/\partial\phi$, and not the radial coordinate. The problem that I want to solve is of course, an Eigenvalue problem which is minus \hbar^2 generally, a particle of mass m , $\nabla^2 \psi$ of $r \theta \phi$. This is the p^2 by $2m$ part plus V of r , ψ of $r \theta \phi$ is $E \psi$ of $r \theta \phi$.

(Refer Slide Time: 05:35)

$$\nabla^2 = \frac{1}{r^2} \frac{\partial}{\partial r} \left(r^2 \frac{\partial}{\partial r} \right) + \frac{1}{r^2 \sin\theta} \frac{\partial}{\partial \theta} \left(\sin\theta \frac{\partial}{\partial \theta} \right) + \frac{1}{r^2 \sin^2\theta} \frac{\partial^2}{\partial \phi^2}$$

$$\vec{L} = \vec{r} \times \vec{p}$$

$$= -i\hbar \vec{r} \times \vec{\nabla}$$

$$L^2 = (\vec{r} \times \vec{p}) \cdot (\vec{r} \times \vec{p})$$

So, instead of writing ψ as a function of x, y, z I write it in terms of r, θ and ϕ . What I want to check is the following thing. ∇^2 of course, can be written in

Spherical polar coordinates in the following manner: $\sin \theta \, d\theta$ by $d\theta$ plus 1 by $r^2 \sin^2 \theta \, d\theta^2$ by $d\phi^2$. You will recall that in spherical polar these scale factors are 1 , r and $r \sin \theta$ and that is why I have put them out here. That is 1 here and an r^2 there and $r \sin \theta$ the whole square here. Those are the scale factors, when I go from Cartesian to spherical polar so this is ∇^2 and since L is $r \times p$ which is $\mathbf{r} \times \nabla$, L^2 would be $r \times p$ dotted with $r \times p$ and will therefore, involve ∇^2 .

So, I would like to write ∇^2 . I would like to write a relation between ∇^2 and L^2 . Now, if I did that (Refer Slide Time: 00:36) I can reexpress ∇^2 in terms of the radial part $1/r^2 \, d/dr$ of $r^2 \, d/dr$ plus an angular part, which will depend only on L^2 . When L^2 acts on ψ it is obviously going to change only the angular part of the wavefunction.

(Refer Slide Time: 07:36)

Because angular momentum is the generator of space rotations and that will only involve the angular coordinates and therefore, it would be possible to try to do a separation of variables here and write ψ of $r \theta \phi$ as R of r some χ of $\theta \phi$ so that L^2 acts only on χ of $\theta \phi$. The equation would then separate into a radial equation, differential equation and an angular differential equation. We will be solving for the Eigenvalues and Eigenfunctions of L^2 . (Refer Slide Time: 05:35) We will use that

as an input in this equation and we will solve for the Eigenvalues of del square. So, that would be the procedure that we will adopt in this problem.

(Refer Slide Time: 08:22)

Express v^2 in terms of L^2 .

$$(\vec{r} \cdot \vec{p})^2 - r^2 p^2 \quad \begin{cases} [x, p_x] = i\hbar \\ [y, p_y] = i\hbar \\ [z, p_z] = i\hbar \end{cases}$$

$$= (x p_x + y p_y + z p_z)(x p_x + y p_y + z p_z) - (x^2 + y^2 + z^2)(p_x^2 + p_y^2 + p_z^2)$$

$$= x p_x p_x + y p_y p_y + z p_z p_z + x p_x [y p_y + z p_z] + y p_y [x p_x + z p_z] + z p_z [x p_x + y p_y] - (x^2 + y^2 + z^2)(p_x^2 + p_y^2 + p_z^2)$$

In order to write del square, in terms of L square I need to do little bit algebra. First of all, I consider r dot p the whole square minus r square p square. This is the straight forward exercise, but it is worth going through it so that we understand the things do not automatically commute with each other and we put in the appropriate factors which arise because of non-commutativity in quantum physics.

So, this object is x P x so when I expand this gives me x P x x P x that comes out of using terms like this and from this I subtract x square plus y square plus z square times P x square plus P y square plus P z square. Now, it is clear that if I commute x across P x using the fact that the commutator of x with P x is i h cross. I get a term x square P x square similarly, a y square P y square here and a z square P z square there. And that will cancel out with x square P x square plus y square P y square plus z square P z square here.

So, I will be left with terms from here, which involve i h cross. So use the commutator x P x is i h cross similarly, for y and P y and z and P z. So, P x x is x P x minus i h cross. Therefore, what I will be left with here is minus i h cross x P x, minus i h cross y P y minus, i h cross z P z, which is minus i h cross r dot P.

(Refer Slide Time: 10:49)

So, therefore I have $r \cdot p$ the whole square minus $r^2 p^2$ is minus $i\hbar$ cross $r \cdot p$. (Refer Slide Time: 08:22) All these terms continue to survive up to this point. As I have already told you $x^2 p_x^2$ cancels out from here after putting in the commutation relation. Therefore, I am left with minus $x^2 p_y^2$ plus $p_z^2 x^2$ that is the first term. (Refer Slide Time: 08:22) Similarly, plus there is an overall negative sign so minus $y^2 p_x^2$ plus $p_z^2 y^2$ minus $z^2 p_x^2$ plus $p_y^2 z^2$. So, I am left with this.

Now, once more I can do the following. I can write here $y p_y$ as $p_y y$ plus $i\hbar$ cross and this as $p_z z$ plus $i\hbar$ cross. Similarly, here this would be $p_x x$ plus $p_z z$ plus $2i\hbar$ cross. Here too, $p_x x$ plus $p_y y$ plus $2i\hbar$ cross. Therefore, this simplifies to the following: look at this $2i\hbar$ cross $x p_x$ plus $2i\hbar$ cross $y p_y$ plus $2i\hbar$ cross $z p_z$ which is $2i\hbar$ cross $r \cdot p$ minus $i\hbar$ cross $r \cdot p$ so that just gives me $i\hbar$ cross $r \cdot p$. And then of course, I have the following things left behind: $p_y y$ plus $p_z z$ out there plus $z p_z$ times $p_x x$ plus $p_y y$ plus $y p_y$ times $p_x x$ plus $p_z z$. And then of course, I have to subtract out these things: minus $x^2 p_y^2$ plus $p_z^2 x^2$ minus $y^2 p_x^2$ plus $p_z^2 y^2$ minus $z^2 p_x^2$ plus $p_y^2 z^2$. So, this is what I have. Look at these terms and compare this with an object like L^2 .

(Refer Slide Time: 14:03)

$$\begin{aligned}
 L^2 &= (\vec{r} \times \vec{p}) \cdot (\vec{r} \times \vec{p}) \\
 &= (y p_z - z p_y)(y p_z - z p_y) \\
 &\quad + (z p_x - x p_z)(z p_x - x p_z) \\
 &\quad + (x p_y - y p_x)(x p_y - y p_x) \\
 \therefore (\vec{r} \cdot \vec{p})^2 - r^2 p^2 &= i h \vec{r} \cdot \vec{p} - L^2 \\
 \vec{r} &= r \hat{e}_r \\
 \vec{p} &= \hat{e}_r \frac{d}{dr} + \dots \\
 \left(r \frac{d}{dr} \right) \left(r \frac{d}{dr} \right) - r^2 p^2 &= i h \left(r \frac{d}{dr} \right) - L^2
 \end{aligned}$$

So, let us look at L square now. L square is \vec{r} cross \vec{p} dotted with \vec{r} cross \vec{p} . Of course, if you now compare term by term, you will find for instance (Refer Slide Time: 10:49) look at this term. There is an $x p_x x p_y y$ and out here you would see the same kind of term that appears there is an $x p_x x p_y y$, the order is right because p_x can be commuted across y and p_y . So, this is an minus $x p_x x p_y y$ (Refer Slide Time: 10:49) and here I would have plus $x p_x x p_y y$. You can compare it term by term and you find that what occurs here, apart from $i h \vec{r} \cdot \vec{p}$ is minus L square. Therefore, this object $\vec{r} \cdot \vec{p}$ the whole square minus r square p square is $i h \vec{r} \cdot \vec{p}$ minus L square.

Now, I move on to Spherical polar coordinates. First of all I write \vec{r} as $r \hat{e}_r$ and \vec{p} as $\hat{e}_r \frac{d}{dr} + \dots$ apart from minus $i h$ cross which we should remember to put in. But, what matters in $\vec{r} \cdot \vec{p}$ is simply $r \frac{d}{dr}$ and therefore, I have $r \frac{d}{dr}$ times $r \frac{d}{dr}$ which is the first term. Minus r square p square is $i h$ cross $r \frac{d}{dr}$ minus L square so this is the kind of thing that I have, but p square itself is minus $i h$ cross $\vec{r} \cdot \vec{p}$ the whole square.

(Refer Slide Time: 16:45)

So, let me put that down here. Therefore, I have $r \frac{\partial}{\partial r}$ times $r \frac{\partial}{\partial r}$ minus r^2 times minus $i\hbar$ cross the whole square ∇^2 is equal to $i\hbar$ cross $r \frac{\partial}{\partial r}$ minus L^2 . This can be easily done now to say that ∇^2 can be written in terms of L^2 . So, I have $r^2 \nabla^2$ from here is $i\hbar$ cross $r \frac{\partial}{\partial r}$ minus L^2 minus $r \frac{\partial}{\partial r}$ of $r \frac{\partial}{\partial r}$. But I can now write ∇^2 in spherical polar and that expression is given here.

I substitute for ∇^2 from here and then if I check by substituting for ∇^2 here I can show that ∇^2 is $\frac{1}{r^2} \frac{\partial}{\partial r} \left(r^2 \frac{\partial}{\partial r} \right) - \frac{L^2}{r^2}$. The radial parts survive minus L^2 by \hbar^2 cross r^2 . The \hbar^2 cross because we know that angular momentum occurs in units of \hbar cross and therefore, this should carry dimensions \hbar^2 cross square.

So, I scale that out and $\frac{1}{r^2}$, there is a dimension matching ∇^2 has dimensions of $\frac{1}{r^2}$ and that is what happens here. The minus sign is simply kept from here I have merely substituted for ∇^2 from there. And this becomes an important relation between ∇^2 and L^2 . So, this is one way of seeing it. I could have done it by moving onto spherical polar coordinates right at the beginning, could have done it in different ways. It is straight forward algebra, but the result is worth demonstrating. (Refer Slide Time: 08:22) Because, it is matter of exercise it teaches you that right at the very first step you cannot simply interchange $\mathbf{p} \times$ and \mathbf{x} , any way you

wish and have to use the commutator relation and maintain order of things. So, this is what you get for del square.

(Refer Slide Time: 19:48)

Now, let us go back to the Eigenvalue problem. The problem that I have is minus \hbar cross squared by $2m$ del square psi of r theta phi plus V of r psi of r theta phi is E psi of r theta phi. So, this is what I have. I substitute for del square therefore, minus \hbar cross square by $2m$ I should say what those m is all about. Suppose, we were looking at the hydrogen atom problem for instance, it is a two body problem, there is a proton and there is an electron. But, instead of this two body problem I could go to an effective one body problem where there is an origin of coordinates and there is an object here with an effective mass $m_p m_e$ by $m_p + m_e$ which I can call μ or m at a distance r , where r is the radial coordinate. So, this is the equivalent one body problem as you know.

You reduce two body problem to an equivalent one body problem, where this radial coordinate is from the origin of coordinates and there is a reduced mass which is $m_p m_e$ by $m_p + m_e$, if we are talking about the hydrogen atom. Otherwise of course, any two objects whose mass is m_1 and m_2 would be an $m_1 m_2$ by $m_1 + m_2$. So, the m that I write here is essentially this reduced mass perhaps, I can call it m . But, you should remember that by m I mean the reduced mass in the equivalent one body problem.

So, that is what we have here. And in that picture I can now substitute for del square as $\frac{1}{r^2} \frac{\partial}{\partial r} \left(r^2 \frac{\partial}{\partial r} \right) - \frac{L^2}{\hbar^2 r^2}$ by \hbar cross square r

square. This acts on psi of r theta phi plus V of r psi of r theta phi is equal to e psi of r theta phi. This is the Eigenvalue problem that I am ought to solve. It is now clear what del square is, what L square is. Just by identification from here (Refer Slide Time: 16:45) I can write L square.

(Refer Slide Time: 22:42)

The image shows a green chalkboard with handwritten mathematical equations. The equations are as follows:

$$L^2 = -\hbar^2 r^2 \left(\frac{1}{r^2 \sin\theta} \frac{\partial}{\partial \theta} \left(\sin\theta \frac{\partial}{\partial \theta} \right) + \frac{1}{r^2 \sin^2\theta} \frac{\partial^2}{\partial \phi^2} \right)$$

$$= -\hbar^2 \left(\frac{1}{\sin\theta} \frac{\partial}{\partial \theta} \left(\sin\theta \frac{\partial}{\partial \theta} \right) + \frac{1}{\sin^2\theta} \frac{\partial^2}{\partial \phi^2} \right)$$

$$\frac{1}{r^2} \frac{\partial}{\partial r} \left(r^2 \frac{\partial}{\partial r} \right) \psi(r, \theta, \phi) - \frac{L^2}{\hbar^2 r^2} \psi(r, \theta, \phi)$$

$$- \frac{2m}{\hbar^2} V(r) \psi(r, \theta, \phi) = - \frac{2mE}{\hbar^2} \psi(r, \theta, \phi)$$

In the bottom left corner of the chalkboard, there is a small circular logo with the text "NPTEL" below it.

And therefore, L square is minus h cross square r square times 1 by r square sin theta, delta by delta theta of sin theta delta by delta theta plus 1 by r square sin square theta delta 2 by delta phi square. I can cancel r square and therefore, I only have an angular dependence in L square as I would expect. So, this is the expression for L square in spherical polar. I can see that L square depends only upon the angular variables and it is essentially the angular part of del square (Refer Slide Time: 16:45) that is what this equation tells me.

So, when del square acts on a wavefunction which is a function of r theta and phi, this part of del square acts on the radial wavefunction and this on the angular part of the wavefunction. In other words, I can try a separation of variables and write the total wavefunction as r of r some chi of theta phi.

(Refer Slide Time: 24:14)

$$= -\hbar^2 \left[\frac{1}{\sin\theta} \frac{\partial}{\partial\theta} \left(\sin\theta \frac{\partial}{\partial\theta} \right) + \frac{1}{\sin^2\theta} \frac{\partial^2}{\partial\phi^2} \right]$$

$$\frac{1}{r^2} \frac{\partial}{\partial r} \left(r^2 \frac{\partial}{\partial r} \right) \psi(r, \theta, \phi) - \frac{L^2}{\hbar^2 r^2} \psi(r, \theta, \phi) - \frac{2m}{\hbar^2} V(r) \psi(r, \theta, \phi) = -\frac{2mE}{\hbar^2} \psi(r, \theta, \phi)$$

$$\psi(r, \theta, \phi) = R(r) \chi(\theta, \phi)$$

Now, if I did that I have the following equation so this is what I have in my equation and if I write psi of r theta phi as R of r chi of theta phi. So, I can do a separation of variables. I will demonstrate that later perhaps in my next lecture, but right now it is clear that chi of theta phi is an Eigenstate of L square after the separation of variables is done.

(Refer Slide Time: 24:43)

$$L^2(\theta, \phi) \chi(\theta, \phi) = \lambda \hbar^2 \chi(\theta, \phi)$$

$$\chi(\theta, \phi) = \Theta(\theta) \Phi(\phi)$$

$$\frac{d^2 \Phi(\phi)}{d\phi^2} = -m^2 \Phi(\phi)$$

$$\Phi(\phi) = e^{im\phi}$$

$$\Phi(\phi + 2\pi) = \Phi(\phi)$$

$$e^{im(\phi + 2\pi)} = e^{im\phi} \Rightarrow m = 0, \pm 1, \pm 2, \dots$$

So, let me solve for that Eigenvalue equation. I can write L square which is an operator function of theta and phi, acting on chi of theta phi is lambda h cross square chi of theta phi. In fact, if you look at the structure of L square you can see that a further separation

of variables can be done. In fact, I can write $\chi(\theta, \phi) = \sum_{\theta} \theta(\theta) \phi(\phi)$. I will put this into L^2 into the Eigenvalue equation for L^2 . Substitute for L^2 in terms of θ and ϕ explicitly. I can do a separation of variables. I will demonstrate that in detail in the next lecture. But right now I want to point out that after that is done, the equation for ϕ would turn out to be this.

Going from there to this step would be shown in a subsequent lecture as I said, but this would be the ϕ equation and I want to focus attention on this for a considerable part of this lecture. What appears here is the separation constant that you would have when a function of θ is equated to a function of ϕ after you do a separation of variables. So, this is the separation constant. The solution for ϕ is therefore, $e^{im\phi}$, m taking value 0, plus minus 1, plus minus 2 and so on. I want to make an observation here. The fact that m takes these values. The fact that λ should be of the form $l(l+1)$ simply because this is the orbital angular momentum operator and it is orbital angular momentum operator square and therefore, in pattern it should be like the Eigenvalues for the spin square operator, s^2 .

So, the fact that λ can be written as $l(l+1)$ and m takes values like this would restrict l and I will comment about this in the next lecture. But, having said that let me focus on this equation. The wavefunction should be single valued at any physical point and therefore, $\psi(\phi + 2\pi) = \psi(\phi)$. What does that mean? $e^{im(\phi + 2\pi)} = e^{im\phi}$, which implies that m takes these values. So, that is how I get quantization of m , $m\hbar$ actually is the Eigenvalue for L_z . But, the important thing is that the quantization comes because of single valuedness of the wavefunction at a physical point. This is like a phase and therefore, a phase change of $2\pi m$ is allowed. There is certain arbitrariness in the phase of the wavefunction up to $2\pi m$, where m is an integer, but that is all the arbitrariness that is allowed.

(Refer Slide Time: 29:17)

I now want to expand on the phase of the wavefunction particularly, in the context of a very important, enlightening and certainly a very extraordinarily educative paper and this was by Professor Dirac in 1931, in the proceeding of the royal society of London. What Dirac showed in this paper was that quantum mechanics does not preclude the existence of isolated magnetic charges like you have electric charges, which are integer multiples of e or multiples of e . Dirac showed that in quantum mechanics you can also have magnetic charges and they will be quantized in units of some g which is the magnetic monopole, a monopole which is an isolated magnetic charge with magnetic charge g .

Now, in order to get through that result what Professor Dirac did was to talk about (Refer Slide Time: 24:43) the change in phase of a wavefunction, the fact that things should be single valued at a given space time point and so on and so forth. With very little formal mathematical equations, but with extraordinary logic, deductions have been made in this paper on the isolated magnetic charge and the quantization condition referred to as a Dirac quantization condition.

(Refer Slide Time: 31:15)

So, let me now talk about some of the highlights of that paper and sketch for you how exactly that result was obtained. The Maxwell equation in the presence of electric charges, reads $\nabla \cdot \vec{E} = \rho/\epsilon_0$. In the absence of magnetic charges or in the absence of magnetic monopoles, we would have an equation like this. Of course, if you had magnetic charges you should put a ρ_m here, analogous to the ρ that we wrote there. This is what you would have in the absence of magnetic monopoles. In order to worry about whether a monopole exist or not, let us follow Professor Dirac's logic. Suppose I have a point A in space time so the coordinates are x, y, z and t and I have a wavefunction ψ which is a function of x, y, z and t . This wavefunction satisfies a normalization condition, $\int \psi^* \psi dV = 1$.

So, that allows for a phase in ψ . So, instead of ψ I could have well written $\psi e^{i\alpha}$, then ψ^* would be $\psi^* e^{-i\alpha}$ and the normalization condition is still satisfied. So, there is certain arbitrariness in the phase of the wavefunction. Now, suppose the system moves from point A to point B, notice that here ψ is a function of x, y, z and t and therefore, I can write this as some ψ_1 of x, y, z, t , $e^{i\alpha}$ of x, y, z, t . So, there are two objects here which change is space time and then you go from A to B what you can measure is the change in phase of the wavefunction, because the phase changes with space time points.

So, while absolute phase is arbitrary there is certain arbitrariness in the phase. Phase differences between two neighboring points, phase difference in the wavefunction are not arbitrary and in general it can be nonzero. Now, suppose you took the wavefunction from A to a somewhat distant point B, clearly you can think of it as being made up of small paths which take you there. But, since the phase changes from point to point the net change in phase: $\Delta\alpha$ is going to depend upon the path that is taken. Over each of these paths $\Delta\alpha$ is going to be different, because α itself varies from point to point.

(Refer Slide Time: 34:54)

Therefore, we have the following conclusions. There is arbitrariness in the absolute phase of the wavefunction, but phase differences which are path dependent appear when moving from A to B. And therefore, when one goes from A to B and comes back from B to A over a close path we need not expect the net phase to be zero, because this is certain path and the total phase accumulation on this path need not cancel out the phase accumulation on this path. So, that is what I meant by a path dependent phase difference. On the other hand, we know that if you have a wavefunction ψ and another ϕ , this object is the overlap between ψ and ϕ and in fact when mod squares it tells me the probability of agreement of the two states ψ and ϕ .

And therefore, that is ambiguously fixed for a given point which means that the change in ϕ over a closed path from A to B and back to A the change in ϕ should be equal to

the change in psi. So, that you see this is psi star phi and since it is a phase change it comes as e to the minus i alpha here and e to the plus i alpha there or vice versa and cancels out. So, the change in the phase of wavefunction after traversing a closed curve should be independent of the wavefunction itself. It should be the same for all wavefunctions. Change in phase of a wavefunction over a closed curve is independent of the specific wavefunction.

(Refer Slide Time: 24:43) If you go back to this example, that is the kind of thing that is being told the change in phase has to be integer multiples of two phi so that there is single valuedness of the wavefunction and so on and so forth. But now, that is because of arbitrariness in phase, I am now talking about a different issue: how could this change in phase of the wavefunction could have happened? It could happen for the following reason and that is what I will illustrate now.

(Refer Slide Time: 38:30)

Let me start of in general by writing a wavefunction as some psi 1 and any change in phase happens, because of psi 1 of x, y, z and t and any change in phase which I am going to add up here and call it e to the i beta. Suppose, I consider the x component of the momentum operator P x psi, in quantum mechanics this is minus i h cross delta by delta x psi 1 e to the i beta and that object is minus i h cross delta psi 1 by delta x e to the i beta plus i psi 1 delta beta by delta x e to the i beta. Similarly, I can write down expressions for P y psi, P z psi and also E psi similarly, for P y psi, P z psi and E psi is i

h cross delta by delta t psi, psi 1 e to the i beta and that quantity is i h cross delta psi 1 by delta t e to the i beta plus i psi 1 delta beta by delta t e to the i beta.

Now, since the wavefunction is continuous, the derivative of beta the phase should exist. Snd I am going to refer to delta beta by delta x as K x, delta beta by delta y as K y, delta Beta by delta z as K z and by K naught I refer to delta beta by delta t.

(Refer Slide Time: 40:45)

$$\hat{P}_x \psi = e^{i\beta} [\hat{P}_x + \hbar k_x] \psi_1$$

$$\vec{k} = (k_0, k_x, k_y, k_z)$$

$$\vec{k} = (k_x, k_y, k_z)$$

$$\vec{P} \rightarrow [\vec{P} + \hbar \vec{k}]$$

$$E \rightarrow E - \hbar k_0$$

So, this is what I have when I work with the momentum and the energy operator on psi. So, let me look at the structure P x psi is simply minus i h cross. I can write this as P x psi 1 (Refer Slide Time: 38:30) because, minus i h cross delta by delta x psi 1 is P x psi 1. There is an e to the i Beta anyway and then I have plus h cross psi 1 K x so I can also pull this psi 1 out, e to the i Beta is here and I can write psi 1 like this.

Similarly, P y and P z which tells me that if I define an object K which has components: K naught, K x, K y and K z and three vector K which I will refer to as K with components K x, K y and K z. Then definitely this is true. It is P goes to P plus h cross K. Similarly, E goes to E minus h cross K naught. What does this mean? This is how psi 1 behaves when I write psi as psi 1 e to the i Beta. So, whenever there is a wave equation which involves the momentum operator P and the energy operator E and if that wave equation is satisfied by psi, psi 1 satisfies the corresponding wave equation with these replacements.

(Refer Slide Time: 43:00)

Let us put that down here. So, if ψ satisfies a wave equation involving \hat{P} and \hat{E} ; these are operators remember. ψ satisfies the corresponding wave equation with \hat{P} going to \hat{P} plus \hbar cross \mathbf{K} and \hat{E} replaced by \hat{E} minus \hbar cross \mathbf{K} naught. But this is very reminiscent of something that you know. When you learnt about Gaussian variance gauge theory and so on, you realize that when a charged particle is put in the presence of a homogeneous magnetic field, there is a minimal coupling that happens between the charged particle and the field. The minimal coupling prescription was like this. Except, that if the vector potential was \mathbf{a} , \hat{P} was replaced by \hat{P} minus $e \mathbf{A}$ by c and \hat{E} was correspondingly replaced with the scalar potential.

So, given a vector potential \mathbf{A} and a scalar potential ϕ , this change, this replacement is very reminiscent of what happens when a charged particle is put in the presence of a homogenous magnetic field. Now, by sure identification I know that \mathbf{A} can be written as \hbar cross \mathbf{c} by $e \mathbf{K}$. Similarly, ϕ can be written in terms of \mathbf{K} naught, but this is of relevance to me right now. So, \mathbf{A} is minus \hbar cross \mathbf{c} by $e \mathbf{K}$. What is that mean? I can define a magnetic field \mathbf{B} which is ∇ cross \mathbf{A} . From where does this field appear? Let us imagine that this field is because of a nonzero isolated magnetic charge and let say this strength is g , sitting somewhere in space.

(Refer Slide Time: 45:35)

So all I am doing now is to take a wavefunction of a charge particle over a circle and what is change in phase of the wavefunction? The change in phase of the wavefunction can be written as delta beta which is simply integral over the circle. Let me call that C of $\mathbf{K} \cdot d\mathbf{l}$ plus $K_x dx$ plus $K_y dy$ plus $K_z dz$. So, if I defined a \mathbf{K} (Refer Slide Time: 40:45) which had components that I have put down here and I define a $d\mathbf{l}$ which has components dx , dy and dz . Then, in the notation used by Dirac in this paper, this would be the line integral of \mathbf{K} . But this delta beta because I know that delta beta is this object and that is how I got that expression, because K_x is this and K_y is that and so on.

But I also know from Stokes theorem that I can write this object as an integral over the surface that it encloses, the surface that it bounds of $\nabla \times \mathbf{K} \cdot d\mathbf{s}$, again in the notation used by Dirac in his paper. Because this is like the line integral related to the surface integral Stokes theorem and $d\mathbf{s}$ is the surface that I am talking about. So, this is what I have and this object is delta beta. But I also know the following: I know that this is the flux due to this charge that is sitting there, because $\nabla \times \mathbf{K}$ is like the magnetic field. When I do this surface integral it is the flux and analogous to Gauss's theorem in electrostatics since, ϵ_0 is a constant this flux is going to be equal to four pi q. If I had a charge q it would have been an integral over the surface of the field due to this charge and analogous to that I have four pi q here.

(Refer Slide Time: 48:30)

Now, let me examine the various surfaces that are possible here. Consider for instance, the limiting case which is of interest to me. When the curve that bounds the surface, shrinks to a point because the surface becomes a closed surface so it just shrinks to a point.

(Refer Slide Time: 49:04)

Then I know the following: this integral goes to 0 because $d l$ is 0. But, on the other hand there is nonzero magnetic charge there and therefore, the flux is nonzero. If the flux is nonzero, the only way by which I can have a nonzero quantity with this whole thing

going to 0 is if B becomes singular at that point. And therefore, I have a magnetic field which picks up a singularity at one point on the closed surface and suppose, the close surface is simply the point g itself, if the close surface is shrunk. Then I can well imagine that there is a singularity of the magnetic field at the monopole site.

So, I have a singularity of B at the monopole site. That is one aspect that if I define a B, I can still get away with it provided, I have a singularity at one point on any closed surface around the magnetic charge which I consider here. (Refer Slide Time: 49:04) Now, more through the point if the line integral, if the line, the curve is simply reduced to a point there is nothing like a delta beta, delta beta is 0 because I never really went over a path to accumulate a phase. In fact there is a no movement, it is simply a point.

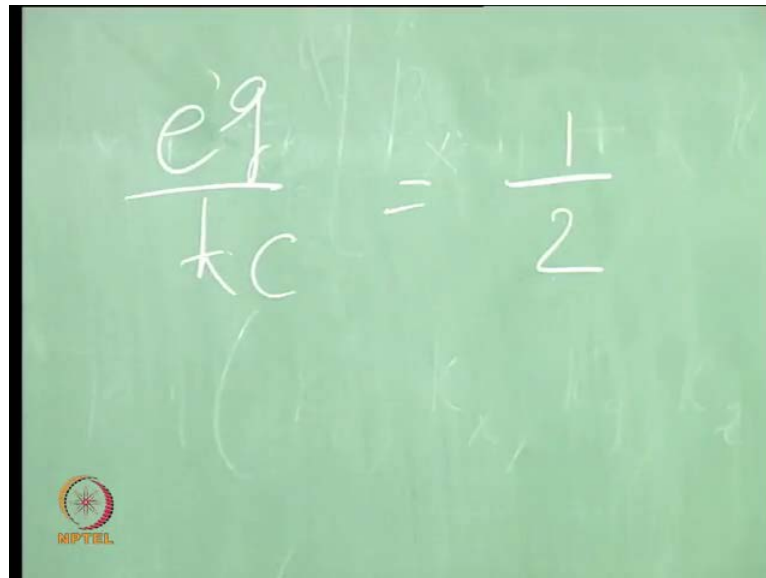

So, let us consider the case of non traversal of any path. In other words, at any physical point delta beta is equal to 0, there is no phase accumulation because no path was traversed. As a digression I should say that if you did traverse a path and somehow accumulated a phase that too can happen in certain contexts and the Berry phases is an example, I will comment about it later. But returning to this, as it is there is arbitrariness in the phase of $2\pi n$. In my earlier example I call that m, magnetic quantum number $2\pi m$, but now I am referring to it as $2\pi n$, where n is an integer 0, 1, 2, 3 anything plus minus 1 and so on. We have to put in that arbitrariness plus $4\pi g$.

(Refer Slide Time: 52:03)

But, it is not just $4\pi g$ because, this is $\text{del cross } K$ and therefore, this is not quite the flux I should be able to write this K as (Refer Slide Time: 43:00) $e A$ by $h \text{ cross } c$. So, I have an e by $h \text{ cross } c$ multiplying A . Instead of K , I write it as $e A$ by $h \text{ cross } c$ and this is in fact the magnetic field so I have a constant e by $h \text{ cross } c$ to reckon with. So, it is $4\pi g e$ by $h \text{ cross } c$. So, look at a situation when $\Delta \beta$ is 0. What does that mean? Let us set n equals 1 that means I am talking about a fundamental pole analogous to e the electrons charge. So, 2π is equal to minus $4\pi e g$ by $h \text{ cross } c$.

(Refer Slide Time: 53:04)

$$\frac{e g}{h c} = \frac{1}{2}$$

So, I have $e g$ by $h \text{ cross } c$ getting quantized now, because $e g$ by $h \text{ cross } c$ is now equal to half (Refer Slide Time: 48:30) I have set n equals 1 otherwise I will have an n by 2. And suppose I look at this as the electrons charge so if I am talking about an electron so I would have had a minus e and that would have canceled the minus sign here. So, in fact I just have $e g$ by $h \text{ cross } c$ equals half. Suppose by this I meant the electronic charge.

(Refer Slide Time: 53:36)

$$eg = \frac{hc}{2}$$
$$\frac{e^2}{hc} = \frac{1}{137}$$

Dirac quantization condn.

$$\therefore g = e \left(\frac{137}{2} \right)$$

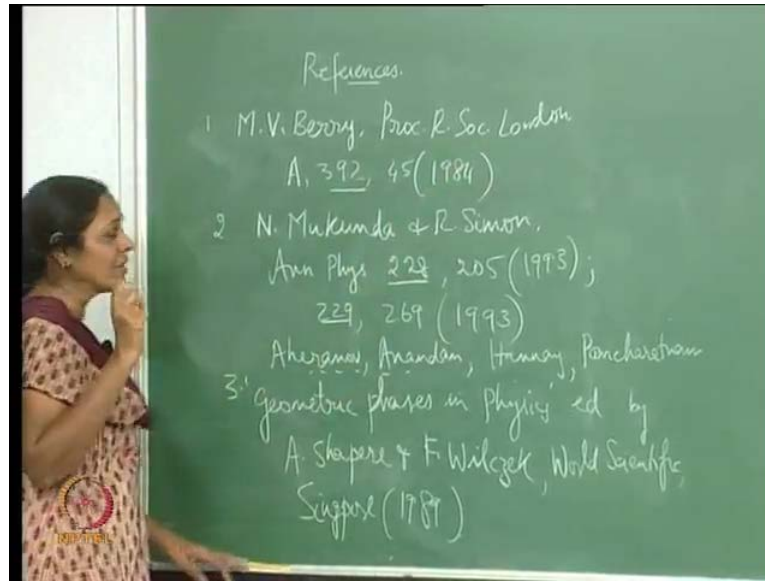

mag charge (Dirac monopole)

Therefore, I have $e g$ by h cross c is half or $e g$ is h cross c by 2, but e square by h cross c is a very small number it is 1 by 137. So, substituting for h cross c into the Dirac quantization condition that is $e g$ is equal to h cross c by 2 into that if I substitute for h cross c . I find that g is very large g is 137 by 2 e and that is the large number.

And therefore, not that quantum mechanics precludes the existence of isolator monopoles. We have just now gone through the entire machinery, as proposed by Dirac. However, it is very difficult to isolate a monopole because monopoles are very strongly interacting with each other, very strongly coupled to each other. So, these are the contents of the significant part of the contents of the paper by Professor Dirac in the proceedings of the royal society. Quite apart from what I have told you here, there is another matter that comes out very clearly and that is this. (Refer Slide Time: 52:03)

If there is a method of producing a net change in phase apart, from the arbitrariness $2\pi n$ which I will not talk about really. (Refer Slide Time: 48:30) That change in phase should come because of effectively a field sitting in the appropriate space. In this case we are talking about the change in phase in physical space, when a wavefunction goes around and that is why the single valuedness of the wavefunction came into effect. (Refer Slide Time: 52:03) However, in a general setting the change in phase would really appear because of an effective field force in an appropriate space and that is what happens in the case of the Berry phase.

(Refer Slide Time: 55:47)

This is very interesting, again very useful and important seminal paper by Professor Berry. I have the reference here. It is M V Berry Proceedings of the Royal Society of London again and this is volume 392 in the year 1984 page 45. Now, it led to an ((Refer Time: 56:03)) of papers, but before I talk about some of the at least or mention some of the at least I want to point out how exactly the Berry phase appears.

(Refer Slide Time: 56:13)

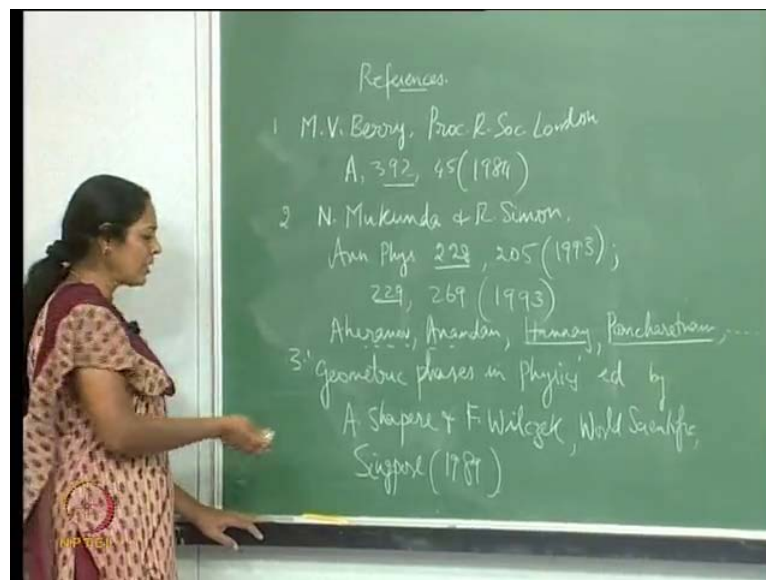

The Berry phase as it is called, it is clear that it comes because of dynamics. Because earlier on I told you that all wavefunctions pickup the same phase when they come back

to a physical point. But there could be small change in the statement if there is an effective field sitting in the space. For instance, suppose I am able to change the parameters in a Hamiltonian. Take for instance the simple harmonic oscillator certainly, one parameter is ω . Suppose, I cycle ω slowly over time and then get back to the original value of ω in general, there can be more parameters. So, in a parameter space which is appropriate for that given physical system, if I did an adiabatic slow cycling of parameters and brought them back to their original value Hamiltonian cannot change its physically measurable.

But then the wavefunction can pick up an extra phase and that is called the Berry phase. The Berry phase could be different for different wavefunctions simply because their dependence on the parameter, each wavefunction depends on the parameters differently. The Berry phase itself is experimentally measurable in certain settings, because I could have a handle on the parameters and the way I cycle the parameters. While the original work done by Professor Berry talks about adiabatic cycling of the parameters and therefore, there is a monopole sitting in the parameters space now, not in physical space. That has been relaxed and in a very general setting where the cycling need not be adiabatic. In fact, it need not be over a closed path, it can even be over an open path.

(Refer Slide Time: 58:30)

Generalizations have been done there are many papers dealing with that but, I mention one of these papers by Professor Mukunda and Simon, this was done in 93. They have

been many names associated with the Berry phase and its classical counterpart, the Hannay angle is the classical counterpart. The Berry phase in the context of optics is a Pancharatnam phase and subsequently many other names have been associated with it.

I put down some of these names and in fact this is an extremely partial list of names. It is for those of you who are interested in knowing something more about the Berry phase, there is this book *Geometric Phases in Physics* edited by Shapere and Wilczek and we should also include their names here in this list. There are many more names. This is to be treated completely as a very partial list of people who have worked on Berry phases.

And in general it is clear that phases are very important some of them are experimentally measurable and one cannot just very casually put aside a statement like the wavefunction is single valued up to an arbitrary phase. It is not just an arbitrary phase you can generate more components to the phase like the Berry phase, or like the phase that led to (Refer Slide Time: 48:30) the monopole quantization. In the next lecture, I will continue where I left off with orbital angular momentum, work out the details of the separation variables and we will take it up from there.
