Fourier Transforms (part III)

(Refer Slide Time: 00:22)

The image shows a chalkboard with two equations written in white chalk. The first equation is the inverse Fourier transform: $f(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} dk e^{ikx} \tilde{f}(k)$. The second equation is the Fourier transform: $\tilde{f}(k) = \int_{-\infty}^{\infty} dx e^{-ikx} f(x)$. In the bottom left corner of the chalkboard, there is a small logo for NPTEL, which consists of a circular emblem with a book and a lamp, and the text 'NPTEL' below it.

So, let us continue with our study of Fourier transforms. The first thing I want to do is to talk about higher dimensional generalization to an arbitrary number of dimensions. I recall that we had think which come like for a function f of x , we had a Fourier transforms which is $\frac{1}{2\pi}$ integral minus infinity to infinity $dk e^{ikx} \tilde{f}(k)$, and the inverse transforms was $\tilde{f}(k)$ was integral dx minus infinity to infinity $e^{-ikx} f(x)$. So, these two functions formed a Fourier transform pair. Now, we can do the same thing in any numebr of dimensions.

(Refer Slide Time: 01:04)

$$\text{In } d\text{-dimensions,}$$
$$f(\underline{r}) = \frac{1}{(2\pi)^d} \int d^d k e^{i \underline{k} \cdot \underline{r}} \tilde{f}(\underline{k})$$
$$\tilde{f}(\underline{k}) = \int d^d r e^{-i \underline{k} \cdot \underline{r}} f(\underline{r})$$

NPTEL

So, if you have a function of a vector \underline{r} in d dimensions say d if d dimensions, then you can define 1 over 2π to the power d integral d dimensional volume integral over all case space, e to the i a dot \underline{r} \tilde{f} of \underline{k} , where \tilde{f} of \underline{k} is integral d dimensional integral over \underline{r} e to the minus i \underline{k} dot \underline{r} f of \underline{x} . So, this is in d dimensions, this stands for the volume integral in \underline{k} space; this for the volume integral in \underline{r} space.

And essentially all the theorms we prove poisson therom and so on and so forth, they are go through in this simple generalization. More interesting than this is what happens if you have a vector valued function, for instance if you have the electric field in some space or magnetic field in space and so on. You can also write Fourier expansions for vector valued function.

(Refer Slide Time: 02:24)

The image shows a chalkboard with three equations written in white chalk. The first equation is
$$\underline{u}(\underline{r}) = \frac{1}{(2\pi)^3} \int d^3k e^{i\mathbf{k}\cdot\mathbf{r}} \tilde{\underline{u}}(\mathbf{k})$$
. The second equation is
$$\nabla_{\mathbf{r}} \cdot \underline{u}(\underline{r}) = \frac{1}{(2\pi)^3} \int d^3k e^{i\mathbf{k}\cdot\mathbf{r}} i\mathbf{k} \cdot \tilde{\underline{u}}(\mathbf{k})$$
. The third equation is
$$\nabla_{\mathbf{r}} \times \underline{u}(\underline{r}) = \frac{1}{(2\pi)^3} \int d^3k e^{i\mathbf{k}\cdot\mathbf{r}} i\mathbf{k} \times \tilde{\underline{u}}(\mathbf{k})$$
. A hand is visible in the bottom left corner, pointing towards the equations. The NPTEL logo is also present in the bottom left corner of the chalkboard image.

So, if you have for instance a vector field \underline{u} of \underline{r} , let us do this in three dimensions, because that is the most common example. So, \underline{u} of \underline{r} is $\frac{1}{(2\pi)^3} \int d^3k e^{i\mathbf{k}\cdot\mathbf{r}} \tilde{\underline{u}}(\mathbf{k})$ this itself a vector of \mathbf{k} in this fashion, so that is the Fourier expansion, and correspondingly there is an inversion formula. Now, the great advantage of Fourier transforms is that just as Laplace transforms converted the operation of differentiation with respect to t to just multiplication by s . And exactly the same way the Fourier transform operation takes spatial derivatives with respect to the components of this factor \underline{r} , and converts them essentially to multiplication by corresponding components of \mathbf{k} .

In the following sense, for instance if you looked at the divergence of \underline{u} , it would be $\nabla_{\mathbf{r}} \cdot \underline{u}$ this is equal to $\frac{1}{(2\pi)^3} \int d^3k$, and then the divergence the derivative with respect to the components of \underline{r} acts on this function here, and what is the divergence of a vector times a scalar. This vector is independent of \underline{r} , so it just it is there ideally. And all that happens is that it is again $e^{i\mathbf{k}\cdot\mathbf{r}}$, and then $i\mathbf{k} \cdot \tilde{\underline{u}}$. So, the operation of $\nabla_{\mathbf{r}} \cdot$ is equivalent to the operation of $i\mathbf{k} \cdot$ on the Fourier component.

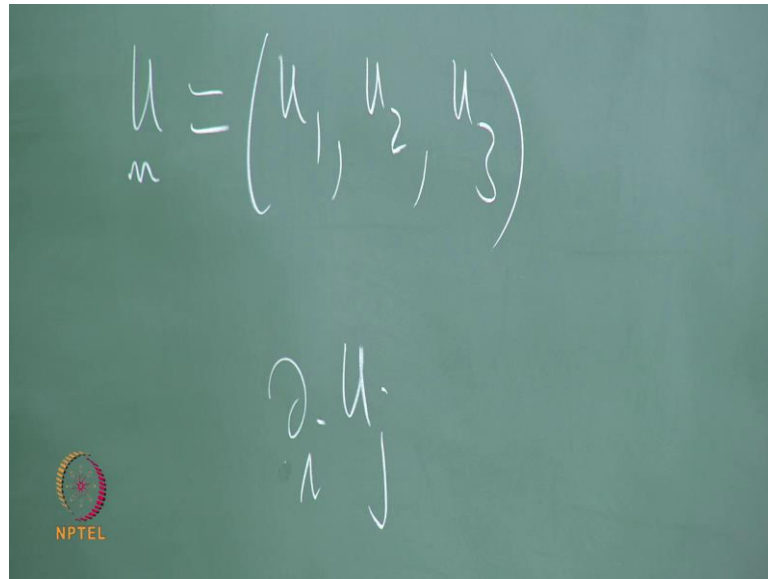

So, if you take the divergence of a vector in three dimensional space that corresponds to taking the dot product with $i\mathbf{k}$ on the Fourier components $\tilde{\underline{u}}$ of \mathbf{k} . In exactly the same way $\nabla_{\mathbf{r}} \times \underline{u}$ of \underline{r} these are all functions of \underline{r} is $\frac{1}{(2\pi)^3} \int d^3k$

\mathbf{k} , again it will be $i\mathbf{k} \cdot \mathbf{r}$ we need the formula for the curl of the vector time is scalar, the vector in this case does not involve \mathbf{r} at all. So, just have one term, and that's $i\mathbf{k} \times \mathbf{u}$ tilde of \mathbf{k} . So, the dot product with ∇ is converted to $i\mathbf{k} \cdot$, and the cross product is converted to $i\mathbf{k} \times$, this means that these operations these partial derivative operations are converted to algebraic operations taking scalar product dot or cross products with this vector $i\mathbf{k}$.

Now, of course as you know in Maxwell equations for example, that is a set of equation in which the spacial derivatives are always see the curls or the divergences of the vector field the \mathbf{a} and \mathbf{b} fields. And if you Fourier transform them, then Maxwell equations get converted to the bunch of algebraic equations for the Fourier transforms. Of course, you also have partial derivatives with respect to time, and therefore you do a Fourier transform with respect to time in the conjugate is the frequency ω . So, derivative with respect to t becomes just multiplication by $i\omega$ or minus $i\omega$ depending on the convention.

So, you can convert Maxwell equations to a bunch of algebraic equations for the Fourier components, and then of course once you solve for that you can re in you can invert the transform in principle to get the original fields. So, it is extremely useful. Now, I tell me why is it just to recall to you, why is it that the differential equation of physics like those in fluid dynamics for instance or in electro magnetism, why do they specify the divergence and curles of a vector field, why not some other derivatives?

(Refer Slide Time: 06:33)

$$\mathbf{u} = (u_1, u_2, u_3)$$
$$\frac{\partial u_j}{\partial x_i}$$

After all if you have a vector field \mathbf{u} , and it is called components u_1, u_2, u_3 say, and ∇ has components $\partial_x, \partial_y, \partial_z$ etc you have 9 possible derivatives, but only one that seems to play a role are the curl and the divergence. So, if you wrote these derivatives down if you wrote $\partial_i u_j$, this stands for $\partial_x u_i$ where i rounds 1 to 3, this is the second rank tensor it is called 9 components. And the divergence is just the sum of the diagonal components, and the curl is just the set of 3 numbers form by taking the differences of the anti symmetric components, why do those two play such a fundamental roles, what is the reason do you, what do you think is the reason?

Student: ((Refer Time: 07:21)) there is given yes, and provided it is well behaved on infinity, then you can find out that.

You can find it you neatly this is called ((Refer Time: 07:32)) theorem, it essentially says that if in a region you specify the divergence and curl of a vector field, and you specify the normal component of the curl on the boundary surface, then the field is uniquely determined by this you know. Now, of course there is one more physical reason why the divergence and curl play a special role, because they have specific transformation properties, this is the second rank tensor here this thing here, but the divergence is the trace of this matrix, and is therefore invariant under rotations. So, it is scalar, transforms like a scalar, on the other hand the curl as you know transforms like a vector.

So, these combinations have well defined transformation properties that is crucial and

what happens? So, in fact what you normally do? If you recall if you look at the multipole expansion for the potential due to an arbitrary charged distribution for instance. Then you have a monopole term which is the scalar, you have a dipole term which is vector, then you have a quadrupole term which is a tensor of rank 2, but very special tensor of rank 2, it does not have nine components, but it has five components. The reason is it is a symmetric tensor.

So, it only has six independent components and then it is traceless, because you get rid of the scalar part which is the trace of the tensor scalar get rid of it, it is already gone in the monopole term subtract it out, and then you left with 5 and so on. So, what happens in general of course is that if you have a tensor of some rank r , then you have 3^r components in three dimensional space, but then when you convert it you remove all the lower dimensional representation of the rotation group, and then of course you get spherical tensor, and the spherical tensor of rank r has $2r + 1$ components.

So, 3^r gets converted to $2r + 1$, in the case of quadrupole 9 components gets converted to 5. The next stage it be 21 components to the next multipole moment, but its gets removed the earlier terms are all subtracted out and then you end up with 7 of them and so on. So, to get back to a viewer the divergence and curl play a very very special role because of this theorem, and we see here that once you have this function $e^{i\mathbf{k}\cdot\mathbf{r}}$ acts like some kind of eigen function for the ∇ operator. And $\nabla \cdot$ becomes $i\mathbf{k} \cdot$, $\nabla \times$ becomes $i\mathbf{k} \times$, therefore life becomes extremely simple once you Fourier transform.

(Refer Slide Time: 10:25)

Now, let us now change topics and go on to a very very important formula in a Fourier analysis, and this is the Poisson summation formula. We come to derive this formula in its simplest form very very elementary form, but it is a very profound result and it has very deep implications in many branches of mathematics. We cannot go on to do the complex complicated parts of it, you are going to see what this formula does for you, and it does something fairly non trivial. In some sense what it does has already been seen by us when we looked at the Fourier transform of a Gaussian.

You recall that if you have a Gaussian function f of x was e to the minus x square over $2\sigma^2$ say 0 mean that's to be simple divided by $2\pi\sigma^2$ a Gaussian centered about the origin. Then the width of this Gaussian, the full width at half maximum for instance is proportional to σ^2 , the larger σ^2 is the wider this Gaussian is and the narrower over it is the smaller σ^2 is that's steeper, the sharper the Gaussian is. On the other hand, these things implied that \tilde{f} of k was equal e to the minus $k^2 \sigma^2$ over 2 .

So, very broad width in x space let to a very small width a very in case base and vice versa. So, if σ is very large this thing here sits here in the numerator as a positive denominator, and just does just the opposite. We saw these terms of the answer in the principle for instance, it is said that if you have a wave packet in x space for the position of a particle, and that is very broad then you expect in momentum space the distribution is

rather sharp and so on and vice versa. Now, the Poisson summation formula generalises this and shows you precisely where this relation comes from.

In fact, it is this case is so important that this is occasionally called the Poisson summation formula, but in the sense of summation which I am going to talk about, but that is this is not it in more general form. So, we start with the following let us start with the function of x which is just a sum of delta functions periodic array of delta function. So, this summation n equal to minus infinity to infinity $\delta(x - nL)$, where L is some length scale some constant positive constant.

Now, what is this function look like? It is just an array of delta function. So, as a function of x there is one at the origin, there is one at L , there is one at $2L$, there is one at minus L , minus $2L$ and so on is just an array of delta function it sometimes called the Dirac comb looks like a comb, and this is just a bunch of Dirac delta functions. Now, we could regard this as a periodic function with the fundamental period that is that lies between minus $L/2$ and plus $L/2$, and this delta function is repeated with the period L , and the fundamental interval is minus $L/2$ to plus $L/2$.

Then of course I can also write this same f of x as equal to $1/L$ summation over n equal to minus infinity to infinity $f(n) e^{2\pi i n x}$, you write it in a Fourier series and the period is L . So, that the Fourier series expansion of this periodic function which is just an array of delta function. This immediately implies that the inversion f of n is equal to an integral from minus $L/2$ to $L/2$ $dx e^{-2\pi i n x} f(x)$, x over L that is the inversion formula for the Fourier coefficients of this function f of x , but in this range this f of x is a single delta function at the origin. So, this guy here is essentially $\delta(x)$ that is the only one which contributes in the fundamental period that will immediately of course we give 1, you put in this delta function and do the integral in a set x is equal to 0 and that is it, it is equal to 1.

(Refer Slide Time: 15:38)

So, going back here this says that $f(x)$ is summation over n , if I do not write limits it means from minus infinity to infinity this for short $\delta(x - nL)$ is also equal to $\frac{1}{L} \sum_n e^{2\pi i n x/L}$. I would like to get read over these $\frac{1}{L}$. So, let us write this as equal to take out the L , so there is a $\frac{1}{L}$ summation over n $\delta(n - \frac{x}{L})$, because we call that the delta function is a symmetric function of its argument $\delta(-x)$ is same as $\delta(x)$.

So, this gives us a very very interesting results. It says a summation over delta functions of the form $\sum_n \delta(n - \frac{x}{L})$ over n is the same as the summation over n of exponentials. So, some of these exponentials is equal to this, and of course you could ask how is going to happened this delta function are all extremely sharp, the answer is of course the destructive interference between these different core science and science are that they cancel each other, and give you essentially peaks from the scale. So, that is the first part or first result that we need.

(Refer Slide Time: 17:26)

The Poisson summation formula:

$$f(x) = \sum_{n=-\infty}^{\infty} \delta(x-nL)$$

$$F(k) = \int_{-\infty}^{\infty} dx e^{-ikx} \sum_n \delta(x-nL)$$

$$= \sum_n e^{-iknL} = \sum_n e^{i2\pi n \frac{kL}{2\pi}}$$

$$= \sum_n \delta\left(n - \frac{kL}{2\pi}\right)$$

Now, let us do the following let us go back here, and say look I am going to regard this function f of x as defined from minus infinity to infinity, and let us do its Fourier transform when what do I get, f tilde of k is equal to summation is equal to an integral minus infinity to infinity $dx e^{-ikx}$ times summation over n delta of $x - nL$, and this is equal to summation over n , and I pick up the contribution from the delta function everywhere. So, it is equal to e^{-iknL} , but since the sum is from minus infinity to infinity, I can change n to $-n$ on the sum does not change.

So, this is also equal to summation of $n e^{iknL}$ just by changing n to $-n$ does not change the summation. And now, I would like to use this formula, I like to use this. So, what I do is to write this as equal to summation over $n e^{2\pi i n x / L}$. So, let me write this, so that it is transparent $2\pi i n x / L$, so $e^{2\pi i n x / L}$ and then there is an x / L and that becomes delta of $n - x / L$ here. So, let us do the same thing here, you have $2\pi i n k L / 2\pi$ and that exactly of this form. So, this becomes equal to where does it go, it is equal to summation over n , a delta function of $n - kL / 2\pi$. So, f of x is this array of delta functions, its Fourier transform Fourier integral Fourier transform is also an array of delta functions from this kind.

(Refer Slide Time: 19:57)

Now, we go back and look at the generalization of the ((Refer time: 19:45)) theorem that we already did use, and what that result said was the following said that if you have two functions f of x and capital F of x , then the integral from minus infinity to infinity dx was equal to 1 over 2π integral minus infinity to infinity in case f tilde of k F tilde of k that was the generalization of ((Refer time: 20:24)) theorem. And if you recall I said if you said this F of minus x capital F of minus x equal to f star of this function, then you got the ((Refer time: 20:34)) theorem which said that $\int |f(x)|^2 dx$ is equal to 1 over $2\pi \int |\tilde{f}(k)|^2 dk$ that is the norms were essentially equated in the k basis and x basis, but this is the generalization of that result.

And now, what I am going to do is to substitute in this equation here, I am going to substitute for F of x from here, and I am going to substitute for f tilde of k from here. The F of x is this delta function array, and incidentally notice also that in this instance F of x is equal to summation over n delta of x minus nL it is also equal to F of minus x , because all I have to do is to change n to minus n , once I put minus x here I change n to minus n then I back to the original formula. So, it is again symmetric and as we saw it is an array symmetrically distributed about x is equal to 0 . So, if I plug that in this immediately says summation over n f of now x is replaced by nL .

So, nL is equal to 1 over 2π integral minus infinity to infinity $dk \tilde{f}(k)$, and then summation over n and this thing here $\delta(n - \frac{kL}{2\pi})$, and I like to do the k

integration. So, I need a delta of k minus something or the other to do that and that's easily obtain, because I can also write this as $\delta(k - \frac{2\pi n}{L})$, and I can take out this constant L over 2π . Now, what is $\delta(ax)$ is equal to where a is a constant, $\frac{1}{|a|} \delta(x)$ and in this case a is L over 2π . So, this becomes $\frac{2\pi}{L} \delta(k - \frac{2\pi n}{L})$ and then there is $\frac{1}{L} \sum_{n=-\infty}^{\infty} \tilde{f}(\frac{2\pi n}{L})$, and I pick this up so summation over n \tilde{f} of $\frac{2\pi n}{L}$.

(Refer Slide Time: 23:26)

So, we have a final result which is the Poisson summation formula, and it says that the f of x is a nice function, when summation over n f of nL where n is L is any arbitrary positive constant, this is guaranteed to be equal to $\frac{1}{L} \sum_{k=-\infty}^{\infty} \tilde{f}(\frac{2\pi k}{L})$. And now let us write this out minus infinity to infinity \tilde{f} , this is the famous Poisson summation formula. So, it says if you sample of function at all the integers some integer multiple of some constant L , you get the same thing as what you get if you sample its Fourier transform at integer multiples of $\frac{2\pi}{L}$.

So, L of course is very large, then the sampling in case space has to be very small sample many very much more frequently. So, notice this is the crucial point that L appears in the numerator here, and it appears in the denominator here this is a conjugate fashion if you like. So, this entire business with delta function and so on and so an artifact, I put L is an arbitrary positive number, for any positive number this is true this relation, and that is the famous this is the summation formula in this instance.

Let us apply it now to the case of the Gaussian which is what I said I would do? And in the case of Gaussian I know what \tilde{f} so I know that f of x is equal to the e to the minus x square over 2 sigma square over square root of 2 pi sigma square, so that is an example. This implies that \tilde{f} of k is e to the minus k square sigma square over 2 .

(Refer Slide Time: 25:38)

Let us put that in, and then you get this very remarkable formula which says summation n equal to minus infinity to infinity e to the power minus instead of f x you put n . So, it is n square L square over 2 sigma square over square root of 2 pi sigma square, this is guaranteed to be equal to 1 over L minus infinity to infinity e to the power minus instead of k you have 4 pi square n square over L square sigma square over 2 . So, let us move this up here, and you have equal to root 2 pi sigma square over L where too many constants here there is L and sigma we can combine these guys.

So, let us combine them in the following way let us put L over root 2 pi sigma square equal to λ say, and then what does this give you? L square over 2 sigma square is pi λ square, so summation n equal to minus infinity to infinity e to the minus pi λ square n square that side is equal to 1 over λ summation is equal to minus infinity to infinity e to the power minus pi, and then 2 pi sigma square λ positive. So, this is an extremely remarkable formula, because it saying something about a sum over the integer of not e to n it is not linear in n , but it is a quadratic in n such sums are called Gaussian sums, they have a large number of weird intricate properties, and the whole

theory of theta functions and so on involves such sums.

Now, notice what is happen it says that sum over such exponentials $e^{-\pi \lambda^2 n^2}$ is equal to the λ appears in the denominator here, and it is an identity. This identity by the way is due to Jacobi and it is so important that is sometimes call the Poisson summation formula itself, but actually the summation formula is this, and that is the special case of it here. Now, lots of implications here, in physical problems you might end up with λ is suitable as a prime meter, and you would like to study it is small λ behavior, large λ behavior and so on.

And now, these two things will give you complementary views for the same thing, for instance in the diffusion problem which will talk about little later, this λ will turn out to be some proportional to the time itself in a diffusion problem turned out to be diffusion constant times t little t . Then we would like to see what the solution of a diffusion equation does for small values of time, and for a large volume by long times. And this identity here will give us a handle on that, this will tell us how which formula is better at small times and at a long times.

It is clear that if λ is very large this dies down as n increases, so you could approximated it with the first few terms, and if λ is small then you would do the same approximation on that sum here, and a different representations all together. Now, one can play this game with any function. So, we already looked at one more example of a probability distribution, and that was a Gaussian distribution let us see what it says in that case.

(Refer Slide Time: 30:24)

So, in case of the Gaussian distribution by f of x was equal to some λ over π times x square plus λ square that is not the ((Refer Time: 30:37)) λ appearance. So, let me call this a for the moment x square plus a square, and what was the Fourier transform of this function f tilde of k was equal to this is a normalised probability density, normalised unity from minus infinity to infinity. And it be it behave like this, this thing or some bell shape curve of this kind, where this width was proportional to a , and f tilde of k in this case was e to the minus λ modulus k a modulus k , it is a characteristic function being the Fourier transform of a probability density.

So, f tilde of 0 must be equal to 1 for normalisation, and what is this function look like? It is a exponentially damped and it is ((Refer Time: 31:34)) per the origin in case x . So, let us plug that in there, let us put that let us put n equal to 1 for instance, and then this says a over π summation n equal to minus infinity to infinity f of n , so that is 1 over n square plus a square recall we already found the sum here, this gives you the lines of function it was π over 2 a caught hyperbolic π a minus 1 over π a or something like that. So, here is another way of doing it, and that is use the Poisson summation formula, and this was equal to summation n equal to minus infinity to infinity f tilde of $2 \pi n$ in this case e to the minus $2 \pi a$ modulus n , we could simplify that.

(Refer Slide Time: 33:02)

$$f(x) = \frac{1}{L} \sum_{k=-\infty}^{\infty} f\left(\frac{2kx}{L}\right)$$

$$\frac{a}{L} \sum_{k=-\infty}^{\infty} \frac{1}{\left(\frac{k}{L} + a\right)^2} = \sum_{k=-\infty}^{\infty} e^{-2\pi a |k|} = 1 + 2 \sum_{k=1}^{\infty} e^{-2\pi a k} = 1 + 2 \frac{e^{-2\pi a}}{1 - e^{-2\pi a}}$$

$$= \frac{1 + e^{-2\pi a}}{1 - e^{-2\pi a}} = \coth \pi a$$

We need to simplify this, so this is equal to, so let us take the term which is n equal to 0 that just a 1 plus twice the summation n equal to 1 to infinity e to the minus 2 pi a, what is this equal to a is some positive number, what is that equal to that is it geometric series. So, it is trivial to sum and this is equal to 1 plus 2 times e to the minus 2 pi a over 1 minus e to the minus 2 pi. So, that gives you 1, so that is equal to 1 plus e to the minus 2 pi a over 1 minus e to the minus 2 pi a multiplied numerator and denominator by e to the pi a, and this a gives you cot hyperbolic pi a.

(Refer Slide Time: 34:30)

So, we back to this result we already know, which essentially says that summation n equal to minus infinity to infinity $\frac{1}{n^2 + a^2}$ is equal to $\frac{\pi}{a} \coth \pi a$. Now, of course what we should do is to separate out n is equal to 0 term rewrite this, so you can rewrite this also as equal to $\frac{1}{a^2}$ plus twice summation n equal to 1 to infinity $\frac{1}{n^2 + a^2}$ equal to that, and then you get the usual expression for this sum. And if you recall in this sum, if I said a equal to 0 what do I get? You get the zeta function for two argument two, so you get $\frac{\pi^2}{6}$ and so on.

You can do this little more generally, you could actually start with f of x , and I will leave that as an exercise to you, start with f of x equal to some $\frac{\cos bx}{x^2 + a^2}$, this whole thing is for b equal to 0, but you can do the same thing the $\cos bx$ here, what you have to do is to find its Fourier transform, and when you do that write this as $e^{ibx} + e^{-ibx}$ over 2 combine it to the k , and then you get once again you get Laurent's ((Refer Time: 36:03)) whose Fourier transform you already know. So, I leave this as an exercise little generalization of this formula.

Now, once again as you would expect this summation formula also is generalizable to high dimension, you can do this in any number of dimensions. So, these things here this n instead of that you have r to pulls of numbers of integers, and you can now do Fourier transforms and higher dimensions is in given analog of this summation formula here, and there are further generalisations. So, there are lots and lots of very interesting results which starts with this very elementary Poisson summation formula, and then go on to do go on to fairly intricate things about the heat kernel it is as an entropic behavior and so on.

We will come back to the use of this formula then we saw the diffusion equation which going to write down the fundamental green function for the diffusion equation, and when we do that we will see the use of this the actual practical use of this formula. In addition of course to the fact that when you have a relation like this, it is useful for summation of series, because there cases when you can sum this and this is harder to do. In this instance for example, this side here was just in geometric series where this side here was much more complicated here. On the other hand you see immediately how this formula is written immediately helps you to find one or more, the left hand side given the right hand side sometimes it happens the other way.

In the Gaussian let us equal in both sides the both Gaussian sums and what we have done is to show that two guys in sums are equal in this specific formula. Many, many other things you can unuse yourself by doing this various other probability distributions in this case, you can see what happens to this formula. So, this is about all I wanted to say about Fourier transforms, we will return to the use of Fourier transforms when we do scattering theory, we want talk about integral equations, and at that time we will come back to this to some of these formulas here and use them in its.
