Lecture - 35
Fluid Flow
Bernoulli's Principle

The equation of motion we have derived for the fluid element leads us to a very important principle, which is very useful in practice called Bernoulli's principle. And today I am going to discuss that along with various other related matters.

(Refer Slide Time: 00:32)

If you recall the equation of motion for a fluid element, so equation of motion of a fluid element was of the following kind, it made a statement about the rate of the change of the velocity field of the fluid element. And it was of the form $\frac{\partial \vec{v}}{\partial t} + (\vec{v} \cdot \nabla) \vec{v}$ was equal to on the right hand side, we had a combination of terms. We had the terms, which went like minus the gradient of the pressure divided by rho plus. So, let us put everything inside minus gradient of pressure over rho plus the potential out here, the potential energy per unit mass of the fluid was sitting here plus where plus is a viscous term.

And if you drop the viscosity of the fluid, assume that the viscosity is low enough that it can be dropped, this in this it flow then this term it throughout and we had an equation of this kind. So, this is not a trivial equation to solve, it is a complicated equation as I repeatedly emphasize. The fact that this \vec{v} appears here and here makes it non-linear and

very, very non trivial to solve, even if you tell me, what the pressure is and what the density is and so on at every point in space and time.

You still have a difficult problem mathematically to solve this equation that was the basic equation of a fluid element here. Now, the way to derive this principle is as follows, is to first of all notice that this term here it should be very gradient of ϕ . It would be useful, if we could write this term here as the gradient of something or the other. But, the gradient of p divided by ρ and if the fluid is not, if it is incompressible of course ρ is a constant it comes out.

But, otherwise you have a ρ here and it is a non trivial function possibly of the pressure, of the density and so on, you know of the velocity etcetera, it is coupled to the velocity. But, we can always write this term as a gradient term as follows in a very special instance and that has to do with bar Barotropic flow. But, before I do that let me come back and say a few things which are implicit in, what I said earlier, but I did not say it as explicitly.

What is a stream line? Well, a stream line is just the feel line of the velocity field in other words, if at some instant of time the velocity vector at this point is in this direction, at this point is in this direction and so on. You join all these up and you get the portrait of the velocity field throughout the fluid at any given instant of time, those are the stream lines. We have statically assumed that our flow is stream line flow, although I did not say it explicitly, this flow is assumed to be stream line flow.

In the sense that at every point it is assume that there is a unique velocity field, the unique direction of the velocity and magnitude of the velocity at very point in the fluid at any given instant of time, now these are the so called stream lines. The line of flow may actually be different in the sense, that if you give me a certain point here, look at a certain point, if this whole flow changes as a function of time, in other words if v has an explicit dependence on time. So, that this derivative is not 0, then if at time t_1 the velocity vector has it is along that direction, at a later time it could be along this or along this and so on.

So, the entire set of stream line could actually change as the function of time. So, this flow lines, then serves could be different, so if you took a given parcel of a fluid it could be on one stream line at a given instant of time and at a later instant it is on a different stream line, it moves this way and so on. So, this could be the path of the parcel of fluid

and it is not on any one given stream line. So, the point is that if the flow is not steady, the stream lines and the lines of flow are different from each other. But, if it is a steady flow, this pattern of the velocity field lines does not change with time.

(Refer Slide Time: 05:16)

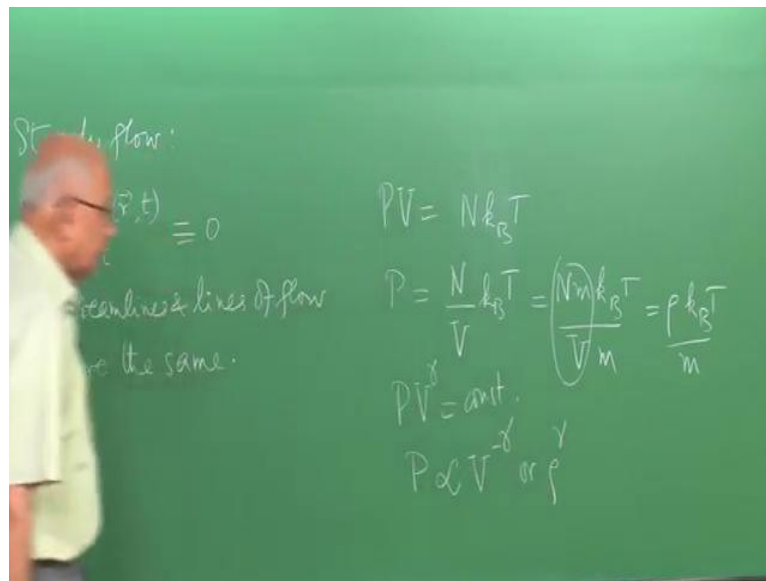

So, a steady flow corresponds to implies that $\frac{\partial \vec{v}}{\partial t}$ is identically 0 at all points, no explicit dependence on time and moreover stream lines and lines of flow are the same. They coincide with each other and that is intuitively obvious, geometrically obvious here, that if the pattern does not change as the function of time, then we say the flow is steady. So, in the case of steady flow we can drop this term here first, so first assumption, let us look at steady flow.

(Refer Slide Time: 06:06)

So, this goes away, because steady flow; this goes away, because I assume that the fluid is inviscid, viscosity neglected, so that gives you a little bit of simplification. Then, we would like to know what this term looks like, in general this term is quite complicated. But, there is one kind of flow called Barotropic flow where it turns out that the pressure is some given function of the density or reciprocally the density is some specified function of the pressure itself. Now, when this is happen? Consider for example, the ideal gas, which we are going to study in some detail a little later.

(Refer Slide Time: 06:58)

In that case you know that $P V$ equal to the number of moles times the gas constant times the absolute temperature here. We could rewrite this in many, many ways we could write this in terms of the total number of particles times Boltzmann constant times T . And therefore, you can have, even write P is N over V k Boltzmann T , where this is the number of particles, it is the volume of the gas and k Boltzmann is Boltzmann constant.

If I multiply top and bottom by the mass of the molecule, then this becomes $N m k$ Boltzmann T over V times m . But, $N m$ over V is the total mass of the gas divided by the volume of the gas in therefore is the mass density of the gas. So, here is an example, at a fixed temperature for an ideal gas the pressure is directly proportional to the density and vice versa. So, this quantity here, we can actually evaluate in this case, because ρ becomes the function of p .

So, for general Barotropic flow implies that P equal to P of ρ or ρ equal to ρ of P . In other words, there is no other dependence, the density depends only on the pressure;

all other variables are irrelevant. In that case, the temperature would have to be kept constant and then, of course you have exactly that situation. In fact, over relation which says P is proportional to ρ directly, but here in general it some non-linear function complicated function of flow.

Another example, if the gas undergoes an adiabatic process then $P V$ to the power γ equal to constant as you know, aware. And since, V is proportional to 1 over the density for a given amount of gas, this says P is proportional to V to the power minus γ or density to the power γ . So, that is another situation where you have a flow of this kind, pressure or density is given some function of the pressure. In that case this term can actually be written down as a gradient of something than the other.

(Refer Slide Time: 09:36)

So, let us see how that happens, gradient of pressure divided by rho if it is a function of pressure alone can be written in the following way. If you have the gradient of some function of the pressure, this is equal to $d f p$ over $d p$ times the gradient of the pressure by gradient time in derivatives with respect to $x y z$ with those unit vectors put in here. So, this is of course equal to the gradient of an integral in definite integral $d p$ over rho of p .

Because, this quantity is an indefinite interval, which is the function of p and its derivative is precisely 1 over rho. So, it is clear that by this rule the gradient of p over rho of p is a gradient of the indefinite integral $d p$ over rho of p and if you tell me p rho as a function of p , I can compute what this function is here in principle.

(Refer Slide Time: 10:53)

Therefore, under these assumptions of steady flow, inviscid flow, Barotropic flow, we finally have statement that $\vec{v} \cdot \nabla$ on the right hand side becomes equal to minus the gradient of integral $d p$ over ρ of p plus ϕ and that is it. Next, let us take the dot product of both sides with respect to \vec{v} , in therefore you have $\vec{v} \cdot$ this quantity equal to minus $\vec{v} \cdot$ the gradient of this scalar quantity. But, look at, what the left hand side is and let's write it out explicitly I do not want to use any vector identity we can simplify this directly.

Just a little bit of algebra, but it is instructive to see, what happens this quantity is a scalar operator, because is a dot product here, it involves derivatives and it acts on a vector to produce a vector and you take the scalar product of that vector with this \vec{v} . So, this thing here should be simplified as follows, let's write out $\vec{v} \cdot \nabla$ is equal to $v_x \frac{\partial}{\partial x} + v_y \frac{\partial}{\partial y} + v_z \frac{\partial}{\partial z}$. Acts on \hat{e}_x on velocity, which is $v_x \hat{e}_x + v_y \hat{e}_y + v_z \hat{e}_z$ in this form and there are nine terms in this expansion, but there finally, easy to write down.

(Refer Slide Time: 12:41)

$$\vec{v} \cdot (\nabla \cdot \nabla) \vec{v} = v_x \left(v_x \frac{\partial v_x}{\partial x} + v_y \frac{\partial v_x}{\partial y} + v_z \frac{\partial v_x}{\partial z} \right) + v_y \left(v_x \frac{\partial v_y}{\partial x} + v_y \frac{\partial v_y}{\partial y} + v_z \frac{\partial v_y}{\partial z} \right) + v_z \left(v_x \frac{\partial v_z}{\partial x} + v_y \frac{\partial v_z}{\partial y} + v_z \frac{\partial v_z}{\partial z} \right)$$

$v_y \hat{e}_y + v_z \hat{e}_z$

So, let us write the first one down this is going to be $v \cdot \nabla$ on v equal to. So, pull the v out all the way to the left and you have $v_x \frac{\partial v_x}{\partial x} + v_y \frac{\partial v_x}{\partial y} + v_z \frac{\partial v_x}{\partial z}$ that takes care of differentiating this term here this three derivatives acting on this term, the next term will be a v_y outside and in v_y . So, we have a v_y plus v_y times this term a when this v_y is done this write, so you have a $v_x v_y v_z$ and then, I am going to take to this v_y and act on that.

So, this is going to be a $v_x \frac{\partial v_y}{\partial x} + v_y \frac{\partial v_y}{\partial y} + v_z \frac{\partial v_y}{\partial z}$ we got do this properly. So, I have v_x , what have by done? I differentiate it v_x each time plus v_y the term is quit correct. So, I have a $v_x \frac{\partial v_y}{\partial x} + v_y \frac{\partial v_y}{\partial y} + v_z \frac{\partial v_y}{\partial z}$, so that is perfectly correct plus v_z times, so we got this term here and it is a v_x acting on this fellow here, so its $v_x \frac{\partial v_z}{\partial x} + v_y \frac{\partial v_z}{\partial y} + v_z \frac{\partial v_z}{\partial z}$, so those are the nine terms here.

And now, add them of in this form here this plus this plus this etc, what do we get, does not the best way to add it up. Now, let us dot this with $v \cdot$, so that is it this is going to be $v_x \frac{\partial v_x}{\partial x} + v_y \frac{\partial v_y}{\partial y} + v_z \frac{\partial v_z}{\partial z}$ and a use the fact that $\hat{e}_x \cdot \hat{e}_x$ is 1 $\hat{e}_x \cdot \hat{e}_y$ is 0 $\hat{e}_x \cdot \hat{e}_z$ is 0 etc. So, dotting this is going to be give me $\hat{e}_x \cdot \hat{e}_x$ is one and its multiplied by a v_x out here. Then, the $\hat{e}_x \cdot \hat{e}_y$ is 0, $\hat{e}_x \cdot \hat{e}_z$ is 0 the v_y part of it is just going to produce a v_y here and the v_z part of it is just going to produce a v_z here that is it and we are in good shape.

(Refer Slide Time: 17:04)

$$\vec{v} \cdot (\vec{v} \cdot \nabla) \vec{v} = (\vec{v} \cdot \nabla) \frac{v^2}{2}$$

$$= v_x \frac{\partial}{\partial x} \left(\frac{v_x^2}{2} + \frac{v_y^2}{2} + \frac{v_z^2}{2} \right) + v_y \frac{\partial}{\partial y} \left(\frac{v_x^2}{2} + \frac{v_y^2}{2} + \frac{v_z^2}{2} \right) + v_z \frac{\partial}{\partial z} \left(\frac{v_x^2}{2} + \frac{v_y^2}{2} + \frac{v_z^2}{2} \right)$$

$$= v_x \frac{\partial (v^2)}{\partial x} + v_y \frac{\partial (v^2)}{\partial y} + v_z \frac{\partial (v^2)}{\partial z}$$

So, we now have a formula which says $\vec{v} \cdot \nabla (v^2/2)$ is equal to $\nabla \cdot \vec{v} (v^2/2)$. Let's collect terms and collect this term, this term, and this term first and note that v_x is a common factor. So, this is v_x times $\frac{\partial}{\partial x} (v_x^2/2 + v_y^2/2 + v_z^2/2)$ plus v_y times $\frac{\partial}{\partial y} (v_x^2/2 + v_y^2/2 + v_z^2/2)$ plus v_z times $\frac{\partial}{\partial z} (v_x^2/2 + v_y^2/2 + v_z^2/2)$. Because, $v_y \frac{\partial}{\partial x} (v_y^2/2)$ is half the derivative of v_y square and similarly half the derivative of v_z square.

So, it's v_x times this plus v_y times $\frac{\partial}{\partial y} (v^2/2)$ exactly the same quantity $v_x \frac{\partial}{\partial x} (v^2/2) + v_y \frac{\partial}{\partial y} (v^2/2) + v_z \frac{\partial}{\partial z} (v^2/2)$ plus $v_x \frac{\partial}{\partial x} (v^2/2) + v_y \frac{\partial}{\partial y} (v^2/2) + v_z \frac{\partial}{\partial z} (v^2/2)$, which is up course equal to $v_x \frac{\partial}{\partial x} (v^2/2) + v_y \frac{\partial}{\partial y} (v^2/2) + v_z \frac{\partial}{\partial z} (v^2/2)$, because that is the definition the square was the magnitude of the velocity plus $v_y \frac{\partial}{\partial y} (v^2/2) + v_z \frac{\partial}{\partial z} (v^2/2)$ plus $v_x \frac{\partial}{\partial x} (v^2/2) + v_y \frac{\partial}{\partial y} (v^2/2) + v_z \frac{\partial}{\partial z} (v^2/2)$. But, this looks like $\vec{v} \cdot \nabla (v^2/2)$. So, we finally, have an identity, which says this quantity is equal to $\vec{v} \cdot \nabla (v^2/2)$ this is the scalar quantity scalar operator acts on $v^2/2$, which is, what this quantity is here.

(Refer Slide Time: 19:16)

Putting this back in our equation we, now have a statement which says that 0 equal to minus \vec{v} dot the gradient of integral $\frac{dp}{\rho}$ plus ϕ , whatever be the potential per unit mass of this fluid plus $\frac{v^2}{2}$. I move the thing this side from the left hand side to the right hand side and took the \vec{v} dot outside, so its \vec{v} dot gradient of this. Now, what is the meaning of this statement here, it says that this scalar quantity its gradient has no component along the vector \vec{v} at any point.

But, the vector \vec{v} at any point its direction is actually the stream lines direction. So, it says, that if you have a stream line like this at this point this is the direction of the velocity \vec{v} and this statement says that this scalar function has no component its gradient has no component along this direction at all. Therefore, it cannot change along this direction this scalar function cannot change along this direction if you recall the gradient of a scalar gives me the rate of change of this scalar function along any direction, what, so ever one side dot it with a unit vector of the direction.

In this case the velocity \vec{v} is tangent to the stream lines and it says that at every point this scalar function does not have any change assume move along this tangent. In other words along a stream line as you go bit by bit increment by increment this scalar quantity does not change. So, this is Bernoulli's principle it says that integral $\frac{dp}{\rho}$ plus ϕ plus $\frac{v^2}{2}$ equal to constant on extreme line this is Bernoulli's principle in a general form it does in say it is the same constant on different stream lines.

So, if a fluid flows like this and this is of the other stream line this are the other stream

lines and that is the portrait of all the stream lines this quantity is some constant c_1 on this some other constant c_2 on this some other constant c_3 on this and so on. In general this is, what happens, but otherwise on each given stream line we as said that this quantity is a constant. What are the assumption, that went in to it we set that the flows in this it this no viscosity no dissipative forces be set that the force external force on it is conservative comes from a potential is a gradient of the potential the flow is barotropic.

So, write you have density as the function of the pressure of the fluid and the flow is steady, so Δv over Δt is 0. Under those conditions this quantity is constant on a stream line, now we can immediately apply this to the case of an incompressible fluid there of course the ρ comes out.

(Refer Slide Time: 22:43)

And, if the fluid is incompressible this will immediately in ρp plus ρ times ϕ plus $\frac{1}{2} \rho v^2$ is equal to constant on a stream line ρ just a constant and in take role of $d\phi$ gives you p and that is it this is the form in which you usually familiar with this. In fact if this comes from gravity and you have a flow, which is under gravity for instance, then this is written as $\rho g z$ in general, so p plus $\rho g z$ plus $\frac{1}{2} \rho v^2$ equal to constant this the form, in which you usually learn an elementary treatments, what the Bernoulli's principles.

If it is a gas for instance, then the density is extremely small and in general it terms out that the effect of this pressure difference this gravity a potential difference is very, very negligible. And therefore, if you neglect this, then it says p plus $\frac{1}{2} \rho v^2$ is

constant, which is the form in, which we see, then its most elementary form here. Incidentally, if this is a stream line and you have a pressure p_1 and density ρ_1 here and a pressure p_2 and a density ρ_2 here and a height h_2 and this is a some height h_1 how of the ground level.

(Refer Slide Time: 24:26)

The image shows a green chalkboard with three equations written in white chalk. The first equation is Bernoulli's principle:
$$P_1 + \rho g h_1 + \frac{1}{2} \rho v_1^2 = P_2 + \rho g h_2 + \frac{1}{2} \rho v_2^2$$
 The second equation is the rearranged form:
$$\frac{P_1 - P_2}{\rho} + g(h_1 - h_2) = \frac{1}{2}(v_2^2 - v_1^2)$$
 The third equation is the constant form:
$$+ \rho g z + \frac{1}{2} \rho v^2 = \text{const.}$$

Then, this equation here tells as that p_1 plus $\rho_1 g h_1$ plus 1 half $\rho_1 v_1^2$ square equal to p_2 plus $\rho_2 g h_2$ plus 1 half $\rho_2 v_2^2$ square. The velocity is v_1 here there this velocity speed is v_1 here in v_2 there tells you this. So, it actually says the p_1 minus p_2 over ρ let us take ρ plus g times h_1 minus h_2 equal to 1 half v_2^2 square minus v_1^2 square. So, the change in the kinetic energy if you like is equal to the work done on this fluid by this pressure had on the gravitational potential.

So, the force of gravity and the pressure it together to do work and change the kinetic energy of this fluid and its written in this form. So, this is the form, in which Bernoulli's principle is used very, very half. But, we have a much more general relationship, which actually says that when you have barotropic flow of the steady flow of the barotropic fluid under a conservative external force in the absence of viscosity it is this quantity that is constant along any given stream line here.

Next are like to introduce a slightly more shuttle concept in fluid flow and that has do with circulation this is not generally talk at in elementary level, but I want to do this, because a game we want it seen that fluid flow as offer does a very natural way of understanding set an operations like the gradient of a scalar this the flux of a vector field,

which means the divergences of a vector field the flux per unit volume. There is a one more concept called the circulation of a vector field.

And since, it appears, so half in various applications of vector analysis such as a Maxwell equations in electro magnetism its worth doing it here and I intent do that. Next we will discuss in very elementary terms the concept of the circulation of a vector of a fluid and, what is meant by the curl of the vector should of the velocity, because it has physical implications.
