Lecture – 12
Fundamental theorems of vector calculus: The gradient theorem

Now, we are going to discuss about the Fundamental theorems of vector calculus; fundamental theorems for gradient divergence and curl.

(Refer Slide Time: 00:47)

Fundamental theorem of gradient

$$\int_a^b \frac{df}{dx} dx = f(b) - f(a)$$

According to the fundamental theorem of gradient

$$\int_a^b (\vec{\nabla} T) \cdot d\vec{l} = T(b) - T(a)$$

Path independent

NPTEL

Let us start with the fundamental theorem of gradient. If we integrate over a range from a to b; the differentiated quantity that is the first order derivative df/dx with respect to x , we know we will get $f(b) - f(a)$. The fundamental theorem of gradient says according to the fundamental theorem of gradient. Integration over the range a to b of the gradient of a scalar field T dot $d\vec{l}$ that is a line integral of it is $T(b) - T(a)$; which tells us that the line integral of a

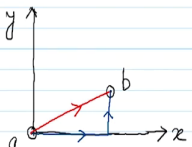

gradient does not depend on the path, it only depends on the values of T at points, at the end points point a and point b .

It does not depend on which path we take to go from a to b . In other words it is path independent. We will not actually prove this theorem; rather we will see examples of it so, that we can work it out whenever necessary.

(Refer Slide Time: 03:13)

Example
Let $T = xy^2$
End points $a(0,0,0)$ and $b(2,1,0)$

Solution
 $\vec{\nabla} \cdot T = y^2 \hat{x} + 2xy \hat{y}$

Path 1: 2 units along x ; 1 unit along y
Path 2: Straight line connecting a and b .

Let us consider an example, let us consider a function scalar field T equals $x y$ squared and we shall check the fundamental theorem of gradient with two end points; a point the coordinate, coordinates are $0, 0, 0$ and point b the coordinates are $2, 1, 0$ in Cartesian coordinate system. So, we can first calculate the gradient of T .

The gradient of T is $y^2 \hat{x} + 2xy \hat{y}$; with this value for the gradient we are suppose to prove that in this Cartesian coordinate system this is the x axis, this is the y axis. We are given two points point a is the origin and point b has the coordinate 2, 1, 0; that is here because there is nothing in the z direction. I did not really plot anything, I did not plot the I did not show the z axis in this picture.

So, here we will consider two different paths; one path would be moving along the x axis for 2 units and then moving along the y axis for 1 unit this and this, this is path 1, path 1. Here we move along the x axis for 1, 2 units, followed by 1 unit along y axis. And we will consider the second path that connects point a and point b with a straight line like this. So, path 2 would be straight line connecting point a and point b; let us consider path 1 first and what it have for that.

(Refer Slide Time: 07:17)

$$\begin{aligned}
 & \text{Path 1} \\
 & y=0 \quad d\vec{l} = dx \hat{x} \quad \text{In the 1st segment} \\
 & \vec{\nabla} T \cdot d\vec{l} = y^2 dx = 0 \\
 & \int_{\text{1st segment}} \vec{\nabla} T \cdot d\vec{l} = 0 \\
 & \text{2nd segment} \quad x=2 \quad d\vec{l} = \hat{y} dy \\
 & \vec{\nabla} T \cdot d\vec{l} = 2xy dy = 4y dy \\
 & \int_{\text{2nd segment}} \vec{\nabla} T \cdot d\vec{l} = \int_0^1 4y dy = 2y^2 \Big|_0^1 = 2 \\
 & \text{1st + 2nd segments} = 2 = \int_a^b \vec{\nabla} T \cdot d\vec{l} = 2
 \end{aligned}$$

For path 1 for the first segment we have $y = 0$; and dl is entirely given by dx in the first segment. We are supposed to write down $\text{gradient of } T \cdot dl$ and this becomes $y^2 dx$; because the gradient of T is $2xy$, but $y = 0$, so $y^2 dx = 0$. And here dl is along the x direction, so no contribution from the y component will come, only the x component contribution will come and that is $y^2 dx$. The value of y is 0, so $y^2 dx = 0$.

With this if we integrate over the first segment in path 1; $\text{gradient of } T \cdot dl$ we will find it to be 0. Now, let us consider the second segment. In the second segment we have $x = 2$ and dl now we are moving along the y direction. So, $dl = dy$. $\text{gradient of } T \cdot dl$ in this direction would only have the y component $2xy dy$; because there is no x component of dl . So, after the dot product the x component will go away. And since the value of x is 2, we can write this as $4y dy$.

Now, if we integrate it over the second segment, $\text{gradient of } T \cdot dl$ we will get the range of integral is here dy changes from 0 to 1, the argument is $4y dy$ and that gives us $2y^2$ over the range 0 to 1 which is nothing but 2. So, from the first segment we got 0, from the second segment we got 2, the sum is 2; that means $\int_a^b \text{gradient of } T \cdot dl$ over path 1 is 2.

(Refer Slide Time: 11:37)

Path 2

$$y = \frac{1}{2}x \quad dy = \frac{1}{2}dx$$
$$\vec{\nabla}T \cdot d\vec{l} = y^2 dx + 2xy dy$$
$$= \frac{3}{4}x^2 dx$$
$$\int_{\text{Path 2}} \frac{3}{4}x^2 dx = \frac{1}{4}x^3 \Big|_0^2 = 2$$

Integration over path 1 = Integration over path 2

Theorem is verified.

Now, let us consider path 2. What do we have in path 2 is, the value of because we are moving over a straight line and the end points coordinate is x equals to y equals 1; the starting point is 0, 0. So, y equals half of x , then dy equals half of dx that is clear. Gradient of T dot $d\vec{l}$ that would become y square dx plus $2xy$ dy . And if we now convert everything in terms of dx , just by the relationship we have found above it would become $\frac{3}{4}x^2 dx$.

Now, we are suppose to integrate over x in path 2; x equals 0 to 2 is the range, we will integrate $\frac{3}{4}x^2 dx$. And as a result we will get $\frac{1}{4}x^3$ 0 to 2 is the range equals 2. So, we can clearly see that the integration over path 1 equals to the integration over path 2.

So, the theorem the fundamental theorem for gradient is verified.
