**Special curvilinear coordinate systems: Cylindrical and spherical**

(Refer Slide Time: 00:32)

Laplacian

$$\nabla^2 \phi = \frac{1}{h_1 h_2 h_3} \left[ \frac{\partial}{\partial u_1} \left( \frac{h_2 h_3}{h_1} \frac{\partial \phi}{\partial u_1} \right) + \frac{\partial}{\partial u_2} \left( \frac{h_3 h_1}{h_2} \frac{\partial \phi}{\partial u_2} \right) + \frac{\partial}{\partial u_3} \left( \frac{h_1 h_2}{h_3} \frac{\partial \phi}{\partial u_3} \right) \right]$$

2 special curvilinear coordinate systems

1. Cylindrical coordinate system  
 $(\rho, \phi, z)$

$$x = \rho \cos \phi \quad y = \rho \sin \phi \quad z = z$$

$$\rho \geq 0; \quad 0 \leq \phi < 2\pi; \quad -\infty < z < \infty$$

$$h_\rho = 1 \quad h_\phi = \rho \quad h_z = 1$$

Now, let us consider special; special curvilinear coordinate system 2 special system. The first one is cylindrical coordinate system; that means,  $u_1$ ,  $u_2$  and  $u_3$  will form a cylinder. How? Let us, draw a cylinder here like this makes a cylinder and the origin of our conventional Cartesian six coordinate system we consider here, this happens to be the X axis this is the Y axis and this is the Z axis.

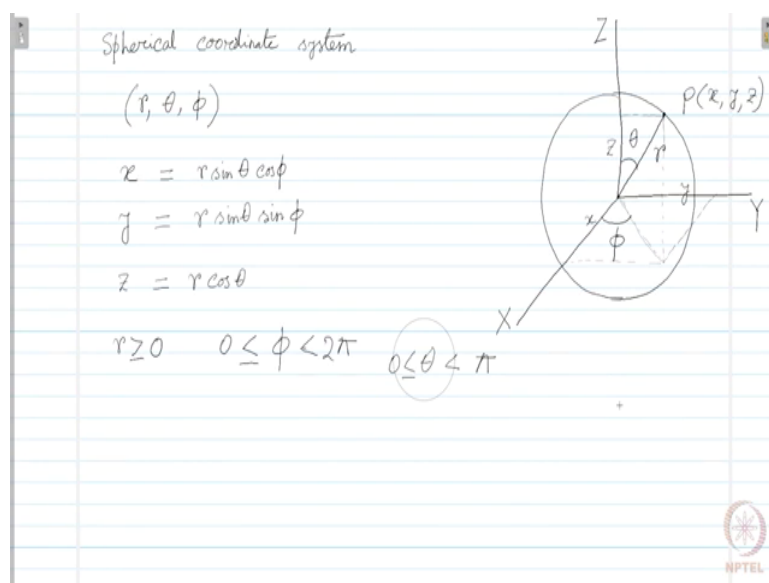

In this notation, if we consider a point P here; this is the position of the point P. Now, the distance of this point P is given distance of this point P from the Z axis is given by rho. And,

the angle that it makes with X axis, so I try to draw a parallel of X axis here the angle that it makes with this is  $\phi$  and the Z value that is this much is given by z. So, we have coordinates  $\rho$ ,  $\phi$ , and z; we also have r  $\theta$  and  $\phi$  coordinates. Sorry, we also have X, Y and Z coordinates of this point P.

Now, if we just compare with our discussion of polar coordinate systems we can write down that x will be given by  $\rho \cos \phi$ , y will be given by  $\rho \sin \phi$ , and z equals simply z nothing else. And there are interesting facts to note that  $\rho$  will always be greater than or equal to 0, there cannot be any negative value for  $\rho$  in this system; in cylindrical coordinate system. The range of  $\phi$  is  $0 \leq \phi < 2\pi$  anything beyond  $2\pi$  is already covered within this range anything less than 0 is already covered within this range.

And z has the limit just like the Cartesian coordinate system, minus infinity less than z less than plus infinity. And in terms of the h components  $h_\rho = 1$  in this case  $h_\phi = \rho$  and  $h_z = 1$ , these are the coefficients to the Cartesian coordinates; that converts it to the Cartesian coordinate system.

(Refer Slide Time: 05:36)

Now, let us consider the other one spherical coordinate system. AC [FL] In case of spherical coordinate system let us try to draw a sphere here and the center of the sphere happens to be the origin of the Cartesian coordinate system this is the X axis of the Cartesian coordinate system this is the Y axis and this is the Z axis.

Now, let us consider a point on the spherical surface point P somewhere here this is our point p now the distance of this point P from the origin that is given as r. So, we found one coordinate r and now we can project this point onto the x y plane say we project it here. So, the x component is this much the y component becomes this much we can see.

Now, if we draw a line from the center to this point on the x y plane then that makes an angle with the X axis that is given as phi and this line marked with r that makes an angle with Z axis that marked with theta. So, we have coordinates r, theta and phi these three coordinates are

there. What are the relations of these coordinates with the Cartesian coordinate system? So,  $P$  has xyz coordinate as well what is  $x$  in our picture?  $X$  is this much,  $y$  is this much, and  $z$  is this much.

So,  $x$  as you can see from this picture we have projected  $r$  on to  $x$   $y$  planes. So, that gives us  $r \sin \theta$ ;  $r \sin \theta$  is this line and then we project this line onto the  $x$  axis. So, the angle is  $\phi$  cosine of  $\phi$  this is  $x$ . Similarly,  $y$  for  $y$  we need  $r \sin \theta$  just because it is projected onto  $x$   $y$  plane and the projection of this line onto  $Y$  axis will bring in  $\sin \phi$  and the  $z$  coordinate is not  $z$ ; it is something else here we have  $r$  and if you project onto  $Z$  axis that will be  $r \cos \theta$  of  $\theta$ .

So, this is the relationship and it is also interesting to note the limits on it  $r$  can never be negative the range of  $\phi$  is from  $0$  to  $2\pi$ , and the range of  $\theta$  it starts from  $0$  and it ends at  $\pi$ ; not  $2\pi$ . Because if we increase the value of  $\theta$   $2\pi$ ; that means, it will  $r$  will actually trace the negative  $Z$  axis and by tracing  $2\pi$  angle using  $\phi$  we can actually trace the entire sphere entire spherical space that is accessible to us and varying the value of  $r$  we can access the whole space. So, we do not need any larger value for  $\theta$  in this case.

So, after introducing the 2 special curvilinear coordinate systems that we are going to use a lot in the course electromagnetism let us consider few examples of these coordinate systems.

(Refer Slide Time: 11:38)

Examples

1. Determine the transformation from cylindrical to Cartesian coordinates

$$\begin{cases} x = \rho \cos \phi \\ y = \rho \sin \phi \\ z = z \end{cases}$$
$$\rho^2 (\underbrace{\cos^2 \phi + \sin^2 \phi}_1) = x^2 + y^2 \quad \rho = \sqrt{x^2 + y^2}$$
$$\frac{y}{x} = \frac{\rho \sin \phi}{\rho \cos \phi} = \tan \phi \quad \phi = \tan^{-1} \left( \frac{y}{x} \right)$$
$$z = z$$

Let us consider the first example where we asked to determine the transformation from cylindrical to rectangular coordinates. How do we do this? We know that; we know the other transformation that is we know that  $x$  is given by  $\rho \cos \phi$ ,  $y$  is given by  $\rho \sin \phi$  and  $z$  equals  $z$ .

So, if we want to find the reverse transformation then we can note that  $\rho$  squared. We are actually squaring and adding these two  $\rho$  squared cosine square of  $\phi$  plus sin square of  $\phi$  this is  $x$  square plus  $y$  square. In other words, so cosine square  $\phi$  plus sin square  $\phi$  gives us 1; in other words, we have  $\rho$  equals  $x$  square plus  $y$  squared square root of this.

Now, if we try to find out  $y$  over  $x$ . So, we divide this equation by this equation here and that gives us  $\rho \sin \phi$  over  $\rho \cos \phi$  which is nothing but  $\tan \phi$ . Then we can clearly understand that  $\phi$  is nothing, but  $\tan$  inverse of  $y$  over  $x$  and  $z$  is  $z$ . So, we have obtained the

reverse transformation; that means, we have determined the transformation from cylindrical coordinate to Cartesian coordinate.

(Refer Slide Time: 14:53)

2. Example of cylindrical coordinate system is orthogonal

$$\vec{r} = x\hat{x} + y\hat{y} + z\hat{z} = \rho\cos\phi\hat{x} + \rho\sin\phi\hat{y} + z\hat{z}$$

Tangent to  $\rho$  curve  $\frac{\partial\vec{r}}{\partial\rho} = \cos\phi\hat{x} + \sin\phi\hat{y}$

$\phi$  curve  $\frac{\partial\vec{r}}{\partial\phi} = -\rho\sin\phi\hat{x} + \rho\cos\phi\hat{y}$

$z$  curve  $\frac{\partial\vec{r}}{\partial z} = \hat{z}$

$$\hat{e}_1 = \hat{e}_\rho = \frac{\partial\vec{r}/\partial\rho}{|\partial\vec{r}/\partial\rho|} = \frac{\cos\phi\hat{x} + \sin\phi\hat{y}}{\sqrt{\cos^2\phi + \sin^2\phi}} = \cos\phi\hat{x} + \sin\phi\hat{y}$$

$$\hat{e}_2 = \hat{e}_\phi = \frac{\partial\vec{r}/\partial\phi}{|\partial\vec{r}/\partial\phi|} = \frac{-\rho\sin\phi\hat{x} + \rho\cos\phi\hat{y}}{\sqrt{\rho^2\sin^2\phi + \rho^2\cos^2\phi}} = -\sin\phi\hat{x} + \cos\phi\hat{y}$$

$$\hat{e}_3 = \hat{e}_z = \frac{\partial\vec{r}/\partial z}{|\partial\vec{r}/\partial z|} = \hat{z}$$

In the next example, we examine where; whether cylindrical coordinate system is orthogonal or not. How do we do that? We considered a position vector in Cartesian coordinate system the position vector  $r$  is given as  $x\hat{x} + y\hat{y} + z\hat{z}$  and that means, in terms of cylindrical coordinate axis we can write it as  $\rho\cos\phi\hat{x} + \rho\sin\phi\hat{y} + z\hat{z}$  this way. Now, the tangent vectors to  $\rho$ ,  $\phi$  and  $z$  curves that can be given as tangent to  $\rho$  curve would be  $\frac{\partial r}{\partial \rho}$  for  $\phi$  curve it would be  $\frac{\partial r}{\partial \phi}$  and for  $z$  curve, it would be  $\frac{\partial r}{\partial z}$ .

So, let us evaluate these quantities  $\frac{\partial r}{\partial \rho}$  is  $\cos\phi\hat{x} + \sin\phi\hat{y}$ .  $\frac{\partial r}{\partial \phi}$  equals  $-\rho\sin\phi\hat{x} + \rho\cos\phi\hat{y}$ , and the  $\frac{\partial r}{\partial z}$  is nothing but;

the unit vector along Z axis. So, we have the unit vectors  $e_1$ ,  $e_2$ ,  $e_3$  that is  $e_\rho$ ,  $e_\phi$ ,  $e_z$  we can determine these unit vectors. So,  $e_1$  that is nothing but  $e_\rho$  becomes  $\frac{\partial r}{\partial \rho}$  over the absolute value of  $\frac{\partial r}{\partial \rho}$ . So, this can be given as  $\cos \phi \hat{x} + \sin \phi \hat{y}$  over  $\sqrt{\cos^2 \phi + \sin^2 \phi}$  which is.

So, the denominator becomes 1 only the numerator remains  $\cos \phi \hat{x} + \sin \phi \hat{y}$ . Similarly,  $e_2$  that is  $e_\phi$  can be given as  $\frac{\partial r}{\partial \phi}$  over the absolute value of  $\frac{\partial r}{\partial \phi}$  that is  $-\rho \sin \phi \hat{x} + \rho \cos \phi \hat{y}$  over  $\sqrt{\rho^2 \sin^2 \phi + \rho^2 \cos^2 \phi}$  square root of this. Which is again we can see that the numerator becomes  $\rho$  squared times one.

So,  $\rho$  squared square. So, this becomes  $\rho$  squared square root that is  $\rho$  and  $\rho$  cancels from the numerator the denominator becomes only  $\rho$ , it cancels from the numerator and we are left with  $-\sin \phi \hat{x} + \cos \phi \hat{y}$ .  $e_3$  is  $e_z$  that is trivial, can be written like this, but it is we know that nothing but  $\hat{z}$ . Now, if we have these we have to now check for the dot products between different unit vectors and see whether it satisfies the condition for being orthogonal curvilinear coordinate system.

(Refer Slide Time: 21:09)

$$\hat{e}_1 \cdot \hat{e}_2 = (\cos\phi \hat{x} + \sin\phi \hat{y}) \cdot (-\sin\phi \hat{x} + \cos\phi \hat{y}) = 0$$

$$\hat{e}_1 \cdot \hat{e}_3 = (\cos\phi \hat{x} + \sin\phi \hat{y}) \cdot \hat{z} = 0$$

$$\hat{e}_2 \cdot \hat{e}_3 = (-\sin\phi \hat{x} + \cos\phi \hat{y}) \cdot \hat{z} = 0$$

3.  $\vec{A} = z \hat{x} - 2x \hat{y} + y \hat{z}$  Represent this in the cylindrical coordinate system  
Determine  $A_\rho$ ,  $A_\phi$ , and  $A_z$

$$\left. \begin{aligned} \hat{e}_\rho &= \cos\phi \hat{x} + \sin\phi \hat{y} \\ \hat{e}_\phi &= -\sin\phi \hat{x} + \cos\phi \hat{y} \end{aligned} \right\} \begin{aligned} \hat{x} &= \cos\phi \hat{e}_\rho - \sin\phi \hat{e}_\phi \\ \hat{y} &= \sin\phi \hat{e}_\rho + \cos\phi \hat{e}_\phi \end{aligned}$$

$$\hat{e}_z = \hat{z}$$

First, let us try  $\hat{e}_1 \cdot \hat{e}_2$  that is  $\cos\phi \hat{x} + \sin\phi \hat{y} \cdot -\sin\phi \hat{x} + \cos\phi \hat{y}$  this turns out to be 0.  $\hat{e}_1 \cdot \hat{e}_3$  equals  $\cos\phi \hat{x} + \sin\phi \hat{y} \cdot \hat{z}$  which is obviously 0 and  $\hat{e}_2 \cdot \hat{e}_3$  is given by  $-\sin\phi \hat{x} + \cos\phi \hat{y} \cdot \hat{z}$  and this is also; obviously, 0. Therefore, the coordinate system that is the cylindrical coordinate system that we have considered and we have worked out so far; turns out to be an orthogonal coordinate system orthogonal curvilinear coordinate system.

Now, let us consider yet another example in cylindrical coordinate system itself. Let us consider a vector  $A$  given by  $z \hat{x} - 2x \hat{y} + y \hat{z}$ . So, this is represented in Cartesian coordinate system and now we want to represent this in the cylindrical coordinate system. What does it mean? That means, we will have to determine  $A_\rho$ ,  $A_\phi$  and  $A_z$ . How

do we do that first we will have to find out the unit vectors e rho, e phi, and e z and we have already found that out in the previous problem; previous example.

So, let us just write that that down e rho is cosine phi x cap plus sin phi y cap e phi is minus sin phi x cap plus cosine phi y cap and e z is z cap. Now, if we compare the first and second unit vectors we can write down by comparing these two that x cap is; cosine phi e rho unit vector minus sin phi e phi unit vector. Similarly, y cap equals sin phi e rho unit vector plus cosine phi e phi unit vector.

(Refer Slide Time: 25:46)

The image shows a handwritten derivation on lined paper. The vector  $\vec{A}$  is defined as  $z\hat{x} - 2xy\hat{y} + y\hat{z}$ . The unit vectors  $\hat{e}_\rho$ ,  $\hat{e}_\phi$ , and  $\hat{e}_z$  are used to express the Cartesian unit vectors  $\hat{x}$ ,  $\hat{y}$ , and  $\hat{z}$ . The derivation proceeds as follows:

$$\begin{aligned}\vec{A} &= z\hat{x} - 2xy\hat{y} + y\hat{z} \\ &= z(\cos\phi\hat{e}_\rho - \sin\phi\hat{e}_\phi) - 2\beta\cos\phi(\sin\phi\hat{e}_\rho + \cos\phi\hat{e}_\phi) + \beta\sin\phi\hat{e}_z \\ &= (z\cos\phi - 2\beta\cos\phi\sin\phi)\hat{e}_\rho - (z\sin\phi + 2\beta\cos^2\phi)\hat{e}_\phi + \beta\sin\phi\hat{e}_z \\ A_\rho &= z\cos\phi - 2\beta\cos\phi\sin\phi \\ A_\phi &= -z\sin\phi - 2\beta\cos^2\phi \\ A_z &= \beta\sin\phi\end{aligned}$$

The NPTEL logo is visible in the bottom right corner of the slide.

Once we have these we can represent the vector A as, z times cosine phi e rho minus sin phi e phi unit vector minus 2 rho cosine phi becomes common sin phi e rho unit vector plus cosine phi e phi unit vector plus rho sin phi e z unit vector that is nothing else, but z cap.

Rearranging these we can write that it is  $z \cos \phi - 2\rho \cos \phi \sin \phi \mathbf{e}_\rho$  unit vector minus  $z \sin \phi + 2\rho \cos^2 \phi \mathbf{e}_\phi$  unit vector plus  $\rho \sin \phi \mathbf{e}_z$  unit vector. And that means, we have actually found out the components  $A_\rho$  is given as  $z \cos \phi - 2\rho \cos \phi \sin \phi$ .  $A_\phi$  is given as  $z \sin \phi + 2\rho \cos^2 \phi$  and  $A_z$  is  $\rho \sin \phi$ .
