General solution (N-dim system)  $\rightarrow$

Eq<sup>n</sup> of motion:

$$T_{ij} \ddot{q}_j + U_{ij} q_j = 0 \quad ; \quad \mathbf{T} \ddot{\mathbf{q}} + \mathbf{U} \mathbf{q} = 0$$

$$Q_k = R_k (C_k e^{i\omega_k t}) \quad Q_k = \hat{a}_{k\alpha} c_{k\alpha}$$

$$q_j = \sum_k g_{jk} Q_k$$

$T_{11} \quad T_{12} \quad \dots \quad T_{1N}$

So, based on the discussion that we have had till now, we are ready to write down the general solution for an N dimensional system which is undergoing some small oscillations near its equilibrium configuration. So, for N dimensional system, so if you take the Lagrangian and from that you write down the equations of motion this is what you are going to get.

So, our equation of motion would be  $T_{ij}$  that is your kinetic energy matrix  $q_j$  double dot of course you have second derivative and then you have the potential energy term  $U_{ij} q_j$  and this is equal to 0. I can write the same equation in matrix form so the same thing looks like this let me write it down on the right-hand side.

So, let me denote by this  $T$  the matrix corresponding to these elements  $T_{ij}$  and then we have  $q$  double dot  $q$  is a column vector plus  $U$  it is a matrix again and then you have the column vector  $q$  and this should be 0. And what we want to do is, we want to write down the general solution for  $q$ . Now, this is not difficult now because we have already done most of the work in fact we have done all the work all we have to do is just write it down.

So, what we will do is we will recall that our system behaves as if it is a collection of  $N$  independent harmonic oscillators, I am assuming all the frequencies to be non-zero here, all the oscillators have non-zero frequencies. So, the picture is the following. So, the system this

system now if you choose the normal coordinates then it looks like the following maybe I should use some, why it does not work? Yes okay.

These pictures will they are not necessary but they do help in remembering certain aspects so yes here, so you have your system appearing as if there are I mean under the right choice of coordinates it appears as if you have several harmonic oscillators, one dimensional harmonic oscillators. And each of them will have a different frequency and I am assuming that they are non-zero right now.

And this will be the coordinate  $q$ , remember this is just a cartoon, so  $q$  and so and oscillators and these  $q_s$  will give you the coordinate which characterizes the displacements. Okay very nice so, now it is clear what the general solution would be, it would be just a linear sum of all these normal coordinates.

Now, what do you have at your hand when you disturb the system? So you can think of your disturbing your system in such a way that you choose to oscillate the oscillator capital  $Q_1$  such that it has a phase  $\phi_1$  at time  $T$  equal to 0 and some amplitude. So, it will have its own amplitude and some phase. This one have will have its own amplitude and some phase and so forth.

So, those are the things which you control, they depend on the initial conditions, because given one dimensional oscillator that is what the freedom you have in choosing. Which means the following that the  $k$ th normal coordinate, I can write as  $C_k e^{i\omega_k t}$  and I should take the real part of it.  $C_k$  is complex which includes the amplitude and the so let us say I write  $C_k$  not here.

So, the phase part of  $C_k$  combines here and gives you the phase of the oscillator  $k$  and the amplitude here the radial part gives the amplitude, so that is what your normal coordinate  $k$  is okay and we already have seen that the transition from your  $q$ , small  $q$  these coordinates to the normal coordinates is through a linear transformation.

Which means I will write down, let me use  $Q$ , I should use black. So, my  $q_j$  the displacement  $q_j$  will be the following, it will be a linear sum of all the one dimensional oscillators and they will all come with some coefficients  $z_{jk}$ , so there is a summation over  $k$  implied here may be I can make it explicit.

And these  $z_i$  will be determined by... we have to calculate, we do not have a control over what  $z_i$  is there should be clear. See what you can control is what is  $C_k$  and  $C_k$  is two

quantities basically the, so if I write  $C_k$  as some  $a_k e^{i\phi_k}$ . So, you can control what  $\phi_k$  is, what  $a_k$  is the amplitude and this.

But beyond that for one dimensional oscillation there is nothing for you to choose and if you can reduce your system to  $N$  oscillators each of them one dimensional you correspondingly choose the  $\phi_k$  and  $a_k$  for each of them and beyond that you have no freedom left to choose anything, which means that this  $z_i$  is completely determined by the problem itself there is nothing for you to choose. This is the point I wanted to make. I will remove this now okay good, yes.

(Refer Slide Time: 08:47)

General solution ( $n$ -dim system)  $\rightarrow$

Eq<sup>n</sup> of motion:

$$T_{ij} \ddot{y}_j + U_{ij} y_j = 0 \quad (1)$$

$$Q_k = \text{Re}(C_k e^{i\omega_k t})$$

$$y_j = \sum_k \xi_{jk} Q_k$$

$$= \sum_k \xi_{jk} \text{Re}(C_k e^{i\omega_k t})$$

Substitute in Eq of motion

$$\sum_k \left[ \sum_j T_{ij} \xi_{jk} \text{Re}(-\omega_k^2 C_k e^{i\omega_k t}) + U_{ij} \xi_{jk} \text{Re}(C_k e^{i\omega_k t}) \right]$$

$$T \ddot{y} + U y = 0$$

$$\sum_k \left[ \sum_j T_{ij} \xi_{jk} + U_{ij} \xi_{jk} \right] C_k e^{i\omega_k t} = 0$$

$\xi_k$  is column vector

$$(\xi_k)_j = \xi_{jk}$$

$$\Rightarrow -\omega^2 T \xi + U \xi = 0$$

suppress the index  $k$

$$U \xi = \omega^2 T \xi$$

Generalized eigenvalue problem

So which is basically I can write this as  $Z_{ij} \xi_j$  times real part of may be in the next line  $Z_{ij} \xi_j$  times real part of  $C_k e^{i\omega_k t}$ . Note that your  $Z_{ij}$  all these elements are also real they have to be real because here  $q_j$  is a real and this part is real so this has to be real otherwise your displacements would not be real.

And I have already made the assumption that I am taking all the omegas to be non-zero. Now, I take this  $q_j$  and substitute in my equation of motion. So, substitute in the equation of motion and what do I get I get the following. So, you already have a summation over  $j$  in this implied here which I have not made it explicit but now I will.

So, I had summation over  $j$  and then I have a summation over  $k$  then your  $T_{ij}$  here  $T_{ij}$  then you have your I have to substitute  $T_j$  I had take the second derivative which brings the  $i\omega_k^2$  which gives a minus  $\omega_k^2$ . So, I get  $Z_{ij} \xi_j$  then your real part of minus  $\omega_k^2$  then you have a  $C_k$  here then you have  $e^{i\omega_k t}$ .

And then you have your potential energy term which gives you the following  $U_{ij}$  may be the I can write down in the next line plus  $U_{ij} x_i x_j$  and then real part of  $C_k e^{i \omega_k t}$ , so that is what you have. We can collect certain terms here and write it in the following fashion. So, from here so now I have summation over  $k$  and I am going to use matrix notation, so I am going to write the summation over  $j$  using matrix notation.

So, this  $t_{ij}$  is our matrix  $T$  and  $Z_i$   $j$ , so it is basically  $Z_i$  is getting dotted into the  $T$  that is the product let me write down and then maybe it will be easier to see what I am trying to say here. So, minus  $\omega_k^2 T Z_i$  of  $k$  I will tell you what  $Z_i$  of  $k$  is in a moment plus  $U Z_i$  of  $k$  okay, okay fine, yes I should have guess why no problem,  $e^{i \omega_k t}$  sorry this is  $c_k e^{i \omega_k t}$  equal to 0.

So, let me tell you what  $Z_i$   $k$  is, your  $Z_i$   $k$  is a column vector you see  $Z_i$   $k$ , this  $Z_i$   $k$  does not carry two indices does not carry  $j$ , so it only one so it is a different quantity and what I have done is a have  $Z_i$   $k$  as a column vector, column vector who's  $j$ th element, so if you look at this vector and look at its  $j$ th element this is  $Z_i$   $j$ . Okay that is the definition of this column vector  $Z_i$ ,  $Z_i$   $k$ .

And if you see this result this expression, we have sum over  $k$  and on the right-hand side you have 0 and each term corresponding to each  $k$  comes with the coefficients  $c_k$  which you control and everything here in these curly brackets is not controlled by you. So, if this entire thing has to sum up to 0 it better be that the term in the curly brackets vanish.

Otherwise it is not possible to make it 0 for whatever  $C_k$  you choose because  $C_k$ s are in your hands, so for that to happen this quantity in curly bracket should vanish and let me write it down. So, this implies that your minus  $\omega_k^2 I$  am just dropping the  $k$  for moment not for... I am just dropping it. So, the following should happen.

So,  $T Z_i$  plus  $U Z_i$  should be clue to 0 because your  $c_k$  are arbitrary, determined by the initial conditions. So, that is what the  $Z_i$  should satisfy as I was saying earlier here that this are determined by the problem the  $Z_i$   $k$  and that is what you see now that the  $Z_i$   $k$  are determined by this equation I have just suppressed the index and you will see immediately why I have done so, okay and this equation which you have here let me write it slightly differently you can write is as  $U Z_i$  as  $\omega_k^2 T Z_i$ , this is called the generalized Eigenvalue problem.

The normal Eigen value problem would be like  $U$  of  $Z_i$  is equal to some constant times  $Z_i$  this is the normal Eigenvalue problem but this is what is called generalized Eigen value problem instead of having your right hand side being proportional to  $Z_i$  you have a constant and again a matrix time the  $Z_i$ . This is called generalized Eigenvalue problem.

Now, you see if I give you system and ask what are its characteristic frequencies what are the frequencies of the normal modes you do not have to first put the Lagrangian in as a sum of squares which the way I was telling you earlier. You can simply do the following, you look at this equation and from here we can conclude how to find out the Eigen frequencies.

And simple because these are set of liner equations let me write it down in the following form.

(Refer Slide Time: 17:48)

$(\omega^2 T - U) \xi = 0$   $\Leftarrow$   
 $\rightarrow$  Linear, homogeneous equations  
 How many equations?  
 A:  $\square$   
 $\det(\omega^2 T - U) = 0$   
 $\rightarrow$  gives the characteristic frequencies.  
 Most gen sol:  
 $q = \sum_k \text{Re}(C_k e^{i\omega_k t}) \xi_k$

$\bullet$  Or:  $\xi_k$  eigenmodes which are orthogonal to each other.  
 $\rightarrow$  Goldstone.

General solution (N-dim system)  $\rightarrow$

Eq<sup>n</sup> of motion:  $T_{ij} \ddot{q}_j + U_{ij} q_j = 0$  (1) :  $T \ddot{q} + U q = 0$

$Q_k = \text{Re}(C_k e^{i\omega_k t})$   
 $q_j = \sum_k \sum_{jk} S_{jk} Q_k$   $\omega_k \neq 0$   
 $= \sum_k S_{jk} \text{Re}(C_k e^{i\omega_k t})$

Substitute in Eq of motion  
 $\sum_k \sum_{ij} [T_{ij} S_{jk} \text{Re}(-\omega_k^2 C_k e^{i\omega_k t}) + U_{ij} S_{jk} \text{Re}(C_k e^{i\omega_k t})]$

$\xi_k$  is column vector  
 $(\xi_k)_i = S_{jk}$   
 $\Rightarrow -\omega_k^2 T \xi_k + U \xi_k = 0$   
 suppress the index k  
 $U \xi = \omega^2 T \xi$   
 generalized eigenvalue problem

I write it as  $\omega^2 T - U, Z_i = 0$ . These are linear homogeneous equations, how many of them are there? These are how many questions? Please supply the answer here. Now, if this set of equations has to have a non-trivial solution, meaning a non-trivial  $Z_i$  which will make this happen then it is necessary that we should have determinant of  $\omega^2 T - U$  equal to 0.

So, if we can solve this equation which is a polynomial equation of degree what you find here. And then you can solve the polynomial equation and get the characteristic frequencies, so this will give you okay it may also happen that some of your  $\omega^2$  turn out to be 0, but that is fine. Now, let say I want to write down the most general solution to our problem where the frequencies are non-zero then it would be just this, this  $q_j$ .

So, your most general solution is  $q$  let me write down the solution in the matrix notation so  $q$  is a column vector here. So, you had a  $q_j Z_i^{(k)}$  now this will become a column vector  $Z_i^{(k)}$  okay. And these are anyway here. So, your most general solution is the following. And let me make the summation over  $k$  explicit, also I would request you to check that this problem if you are looking at this generalized Eigen value problem.

The  $Z_i^{(k)}$  in our case is a set of Eigen vectors which are which are orthogonal, orthogonal to each other okay you will be able to do this based on the discussion which we have had in the last couple of hours or you can also refer to some book like Goldstein, okay so we have written down the general solution and will continue with more discussion on harmonic oscillations or small oscillations in the next video.
