KEPLER'S THIRD LAW

Angular momentum $\Rightarrow \frac{dA}{dt} = \frac{l}{2\mu}$ ← Second law

T : $A = \pi ab$

$A = \pi ab = \frac{l}{2\mu} T$

$b = a\sqrt{1-e^2} = \sqrt{\frac{l^2}{\mu k}}$

$T = 2\pi \cdot a^{3/2} \sqrt{\frac{\mu}{k}}$

$T^2 = (2\pi)^2 \cdot \frac{l}{\mu} \cdot a^3$

(Time period)² = const. (Semi-major axis)³
Third law

Let us, begin by deriving Kepler's Third Law in this lecture. As you may recall from angular momentum conservation we concluded the Kepler's second law which says that the radius vector sweeps equal areas in equal times. So that is what was second law and let me write it down angular momentum implies that dA over dt is a constant and that turned out to be l over 2μ this is what your second law is.

Now, if let us say we are looking at ellipse elliptical orbits then if it takes a time T which I write this capital T to complete one orbit, then in the time T the radius vector is going to sweep an area A which is equal to the area of ellipse that is π times a times b , a and b are semi-minor and semi-major axis there is the area of ellipse.

So, in this time T this much of area will be covered and if you use your second law here and integrate this equation, you can get you will get A is equal to and I am integrating this one and I am just writing what value it is. So l over 2μ times T , I am just done an integral. Now, you

recall how semi-major axis sorry semi-minor axis is related to semi-major axis and the relation if you recall is this, and if you substitute the values you will get a square root of a l square over mu k in the square root.

Now, if you substitute a, a is anywhere here if you substitute b in this expression will get the following. You will get that T is equal to 2 Pi the algebra is simple you have to just plug in few quantities here a to the 3 half mu over k in the square root which means you are T square if you square both sides 2 Pi square and you have a mu over k times a cube which says that time period square is equal to a constant times semi-major axis cube and this is your third law.

So, for given two body system the mu is fixed and so this piece is truly a constant and this is how you are time periods are related to semi-major axis cubes and that is what is the third law is. Next I want to talk about a special vector that is conserved when you are looking at Kepler problem and this is called Laplace Runge Lenz vector and that is what I am going to look at now.

(Refer Slide Time: 05:07)

LAPLACE-RUNGE-LENZ vector

Define $\vec{A} = \vec{p} \times \vec{L} - \mu k \frac{\vec{r}}{r}$

Ex: Argue that \vec{A} lies in the plane of motion.

$$\frac{d\vec{A}}{dt} = \underbrace{\dot{\vec{p}} \times \vec{L}}_I + \underbrace{\vec{p} \times \dot{\vec{L}}}_0 - \mu k \frac{d}{dt} \left(\frac{\vec{r}}{r} \right)_II$$

$$I: \dot{\vec{p}} \times \vec{L} = \left(-\frac{k}{r^2} \vec{r} \right) \times \left(\vec{r} \times \mu \dot{\vec{r}} \right) = -\mu k \left[\frac{\dot{r}}{r} \vec{r} - \frac{\dot{\vec{r}}}{r} \right]$$

$$II: -\mu k \left[-\frac{\dot{r}}{r} \vec{r} + \frac{1}{r} \dot{\vec{r}} \right]$$

$I + II = 0$
 $\frac{d\vec{A}}{dt} = 0$; \vec{A} is a conserved vector

So, we will talk about Laplace Runge Lenz vector. So, out of the momentum, angular momentum and the radial vector the radius vector which gives the location of the particle. Let us, define a quantity which I denote by A as follows. So, I take the cross product of the momentum of the particle mu wherever it is with the angular momentum which is conserved. This is a cross product and from this you subtract mu k times the unit vector unit radius vector so I have divided by r which makes this quantity a unit vector.

A small exercise trivial one basically argue that A lies in the plane of motion. So, you should argue that A the vector A is a vector which is in the plane in which the particle is moving that is fairly simple exercise. Now, I want to show that this is a conserved quantity meaning I want to show that if I take the time derivative of A , I will get 0 that is what I want to show.

So, let us calculate the derivative. So, I have $\mathbf{p} \times \mathbf{l}$, so first $\dot{\mathbf{p}} \times \mathbf{l} + \mathbf{p} \times \dot{\mathbf{l}}$ that is good minus μk , I have $\frac{d}{dt}$ of this I will save it for later. Now, this is 0 immediately. Why? Because \mathbf{l} is conserved, so $\dot{\mathbf{l}} = 0$ and that is what is here. You have $\dot{\mathbf{p}} \times \mathbf{l}$ so it that is 0 so this is gone and let us now look at these two terms 1 and 2.

So, term 1 is a following so I have $\dot{\mathbf{p}} \times \mathbf{l}$. Now, $\dot{\mathbf{p}}$ is the force, the rate of change of angular momentum is force and our force is minus k over r^2 in the radial direction which I will write as minus k over r^3 and I write $\hat{\mathbf{r}}$ here which makes it go as 1 over r^2 and the direction is captured correctly here.

So, you have $\dot{\mathbf{p}} \times \mathbf{l}$ now let us multiply with this across with this angular momentum and angular momentum is $\mathbf{r} \times \mathbf{p}$ which I write as $\mathbf{r} \times \mathbf{p}$ would be $\mu \mathbf{r} \times \dot{\mathbf{p}}$ that is good. This is same as maybe I will leave it as an exercise. See you have here $\mathbf{r} \times \mathbf{r} \times \dot{\mathbf{p}}$ and this I will just write down the result it is simple algebra you can do.

So the result will be minus μk then you have $\dot{\mathbf{r}}$ so there is no vector here this is just $\dot{\mathbf{r}}$ the radial velocity over r^2 times \mathbf{r} vector minus $\dot{\mathbf{r}}$ over r it should be not very difficult to obtain then the term number 2, you can check it will has simple derivative so you have you will get minus μk and then you will have minus $\dot{\mathbf{r}}$ over r^2 times \mathbf{r} vector plus 1 over $r \dot{\mathbf{r}}$.

Now, let us see what is sum of 1 and 2 so you minus have μk these are common here in both. So, you have $\dot{\mathbf{r}}$ over r^2 \mathbf{r} , $\dot{\mathbf{r}}$ over r^2 \mathbf{r} with a minus sign so that cancels against this one and similarly the second one also cancels. So 1 plus 2 is 0 which means $\frac{dA}{dt}$ is also 0 which would imply that A is a conserved vector, and this is Laplace Runge Lenz vector is.

Now this is a conserved quantity so should you be expecting a symmetry which will lead to this conservation I will leave you with that thought about this. Now, what you can ask about this vector A . Now, you may think what is the magnitude of this vector A and where is this vector located ofcourse it is going to be fixed in space and not change with time because this is

conserved and you would like to know where that vector A is located and what is its length that is what we want to take up next.

(Refer Slide Time: 12:04)

So, it will be very useful to mark all the quantities which are related to ellipse before I calculate the magnitude and direction of that Laplace Runge Lenz vector. So, I have drawn an ellipse here and let me just fill some of the details here is the focus this point is called perihelion so some nomenclature I want to throw, perihelion this point the opposite point which is furthest away from the focus is called aphelion.

Let me also write down the equation which we wrote some time back this is a times 1 minus ϵ square ϵ is the eccentricity and you have 1 plus ϵ cos of θ . This length is from here to here the place where θ is π by 2 is a times 1 minus ϵ square that is correct this is the closest distance and this is a times 1 minus ϵ and from the centre of the ellipse to the focus is a times ϵ .

Let me denote also by these, perfect and this the rectangle which you see here is $2a$ from here to there and this length is $2b$ from here to there. Now, we want to know the magnitude of a so you can choose any point in the orbit and try to calculate the vector a , so you find out what is the momentum at that point let us say you choose the point over here. So, you should find out what is momentum there and angular momentum is anyway fix so there is nothing to get from the orbit and then you find out what is the r for that point.

So, this point and of course it will be best, if you choose this point to calculate a it does not matter where you calculate because it is going to be a constant. It is not going to change. So, let us look at this point and evaluate a in at this point. So, it is here so let maybe I can give expression on next page.

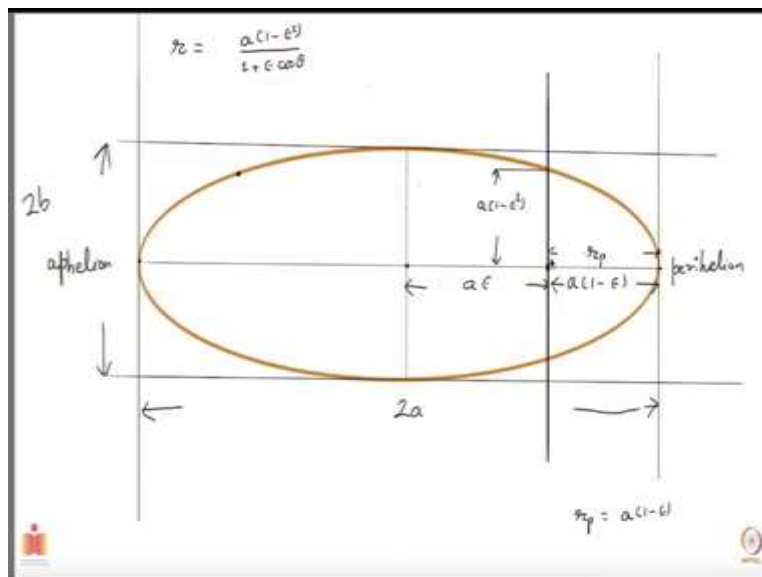

(Refer Slide Time: 15:39)

It is easiest to determine \vec{A} by evaluating it at the perihelion

$$E: \vec{p} \times \hat{L} \Big|_{r_p} = \mu k (1 + e) \frac{\vec{r}_p}{r_p}$$

$$\vec{A} = \mu k (1 + e) \frac{\vec{r}_p}{r_p} - \mu k \frac{\vec{r}_p}{r_p}$$

$$= \mu k e \frac{\vec{r}_p}{r_p}$$

So, it is easiest to determine A by looking at by evaluating it at the perihelion. So, let us do that exercise number 1 trivial; almost trivial. P cross L, we want to evaluate this as at rp so by p I mean perihelion. So, this is the this length from focus to perihelion I am calling rp which is a1 minus epsilon. Please show that this is equal to the following mu k 1 plus epsilon a k is the thing which appears in the potential and (())(16:55) reduced mass epsilon is the eccentricity times rp over rp.

So that is what you should get and maybe I should emphasize that, rp is a1 minus epsilon this is rp. So, that is rp I just removed because I did not want to clutter this page and all you will need to really use is that p and L so the momentum and angular momentum at perihelion would be having 90 degree see here the particle would be going in this direction and angular momentum is anyway I mean sorry angular momentum is anyway perpendicular to r so and p correspondingly.

So that is not the point what I wanted to say was at this play at this point the momentum is also perpendicular to the radial direction. So, this vector and this momentum they will be having 90 degree for the same is not true at any other I mean for example here, or is it, anyhow at this point it is true probably for (())(18:53) may not be true I will I will think about it later.

So, that is one thing you please show and once you have done that our vector A is immediately available to us. So, A would be mu k times 1 plus epsilon rp over r that is the first term minus mu k rp over r and calculating that is also you know it is quite easy this not much and with that you will get the following.

So, you have μk and $1 + \epsilon - 1$ will give you ϵ and then you have r_p over r which is just the unit vector in the direction of perihelion. So, that is the Laplace Runge Lenz vector. So, I will stop this video here and will continue further in the next video.
