*Hamiltonian Mechanics continued.*

$$L(q, \dot{q}, t) \longrightarrow H(q, p, t) \quad \text{Q: } \frac{dH}{dt} = ?$$

$$\frac{\partial L}{\partial t} = \frac{\partial H}{\partial t} \quad \leftarrow \quad \begin{aligned} \dot{q}_k &= \frac{\partial H}{\partial p_k} \\ -\dot{p}_k &= \frac{\partial H}{\partial q_k} \end{aligned}$$

$$\frac{\partial L}{\partial q_k} = -\frac{\partial H}{\partial q_k} \quad \dot{q}_k = \frac{\partial H}{\partial p_k}$$

$$\frac{dH}{dt} = \frac{\partial H}{\partial q_k} \frac{\partial q_k}{\partial t} + \frac{\partial H}{\partial p_k} \frac{\partial p_k}{\partial t} + \frac{\partial H}{\partial t}$$

$$\frac{dH}{dt} = \frac{\partial H}{\partial t}$$

If  $L \leftrightarrow H$  does not depend explicitly on time,  $\partial H / \partial t = 0$

$$\frac{dH}{dt} = 0$$

$\Rightarrow$  Hamiltonian is conserved for such systems.

In the last video we saw that we can go from Lagrangian to Hamiltonian through a Legendre transformation. So, I start from  $L$  of  $q$  and  $\dot{q}$  and  $t$  and I go to Hamiltonian which is a function of  $q$ ,  $p$  and  $t$ . And as you may recall I was saying that we are going to treat  $q$  and  $p$  at equal footing and when we went from  $L$  to  $H$  we had the following relations which were true, one is  $\partial L / \partial t$  is same as  $\partial H / \partial t$ .

So, the partial derivatives of  $L$  and  $t$  with respect to time are equal. And also if you take the time (sorry) the derivative of  $L$  with respect to one of the coordinates then it is same as the derivative of the Hamiltonian with respect to the same coordinate except for a minus sign, so these two are identical. And also we had  $\dot{q}$  to be equal to the derivative of Hamiltonian with respect to the corresponding momentum, conjugate momentum. Remember the  $p$  turned out to be the conjugate momentum that you had seen earlier.

So, this is what you these three you have these equalities you have purely arising from you going from  $L$  to  $H$  through Legendre transformations, they do not you did not use equations of motion for these to hold true. So, if you also in further demanded the coordinate  $q$  satisfies the Euler

Lagrange equations of motion from that you can arrive at the following equation of motion which was the following. So, if you look at  $p$  maybe not here,  $p$  if you look at the time derivative of one of the momenta, let us say  $p_k$  then that was same as  $\delta H / \delta q_k$  and there has to be a minus sign here.

So, whenever you are taking the derivative of  $H$  with respect to  $q_k$  not whenever I mean these equations of motion there is a minus sign. And we also said that because you are treating  $q$  and  $p$  at the equal footing we will also treat this one as equation of motion. But remember this this one you did not arrive at by using any Euler Lagrange equations of motion but in the Hamiltonian formalism we are going to treat this at the equal footing to this one.

So,  $\delta H / \delta p_k$  and these are your Hamilton's equations of motion that is fine now let us ask what is the total derivative of Hamiltonian with respect to time? So, I am asking what is  $dH / dt$  and it is easy to evaluate  $dH / dt$  is  $\delta H / \delta q$  and then you have  $dq / dt$  which is  $\dot{q}$  and  $\dot{q}$  is  $\delta H / \delta p$ ,  $\delta p$ , let me put a  $k$ ,  $k$  and that is fine.

So, there is a summation over  $k$  implied here plus I will take now take a derivative of  $\delta H / \delta p$ , because it is also function of  $p$  and there are several of them, so let me call it  $p_k$  and sum over all the case and then you have a  $\dot{p}_k$  here, but  $\dot{p}_k$  is minus  $\delta H / \delta q_k$ , so I put a minus here  $\delta H / \delta q_k$  and then the third term will be the partial derivative of  $H$  with respect to time because you are Hamilton could in principle depend explicitly on time.

But now these two terms are equal, you have  $\delta H / \delta p_k$ ,  $\delta H / \delta p_k$  here,  $\delta H / \delta q_k$ ,  $\delta H / \delta q_k$ , so these two cancel, so let me just cancel them and what you are left with is  $\delta H / \delta t$ . So, the result we get is the total derivative of Hamiltonian with respect to time equals the partial derivative of Hamiltonian with respect to the time.

Okay that is nice and it is a nice result you can say more because you also know that the partial derivative of  $H$  with respect to time is equal to  $\delta L / \delta t$ , now if your Lagrangian did not depend explicitly on time then your will Hamiltonian will also not depend explicitly on time that is what this equation is saying.

So, let us say the explicit time dependence on explicit time dependence is not there and if that is the case then your total time derivative of H will be 0. So, if L or equivalently H does not depend explicitly on time then your this thing is 0. And if that is the case then dH over dT is equal to 0 which means that Hamiltonian is conserved for such system.

And you may also recall that very early in this course we had encountered this quantity pq dot minus L which is what we are calling Hamiltonian here and this is what we call Jacobi's integral in very early lectures and we also saw that this quantity can be identified with total energy if certain conditions are met, it is not always the total energy, but under certain conditions it can be identified with total energy and let me just remind you what those conditions were, you can go back to those early lectures and see.

(Refer Slide Time: 07:57)

$$H(q, \dot{q}, t) = T_2 + U - T_0$$

$$T_1 \quad T = T_2$$

$$U = U(q)$$

$$H = T_2 + U = \text{total energy of the system}$$

$$\frac{dH}{dt} = 0 \Rightarrow \text{Total energy is conserved}$$
 Example: Harmonic Oscillator
 
$$L = \frac{1}{2} m \dot{x}^2 - \frac{1}{2} k x^2$$

$$H = p \dot{x} - \left( \frac{1}{2} m \dot{x}^2 - \frac{1}{2} k x^2 \right)$$

$$\frac{\partial L}{\partial \dot{x}} = p = m \dot{x} \Rightarrow \dot{x} = p/m$$

$$H = \frac{p^2}{2m} + \frac{1}{2} k x^2$$

$$H = E = \frac{p^2}{2mE} + \frac{1}{2} \frac{k x^2}{E} = 1$$

Remember that we showed I think we were calling it small h at that point of time, but the small h and let us call it capital H now but at that time it was being written as q, q dot and t, not as qpt. And we saw that this is T2 plus U minus T naught where the kinetic energy T you can write as T2 plus T1 plus T naught and the terms T1 and T naught are present only if your transformation to generalize coordinates involves time explicitly.

I hope you recall this and if that is the case, if they are explicitly time dependent transformations then you have T0 and T1 as non-zero quantities and this is what you get here then for the Hamiltonian. And in here U is a function of q only the coordinates only. Now, let us suppose that

the kinetic energy  $T$  only equals to the quadratic piece, so it has  $\dot{q}^2$ ,  $\dot{q}_k \dot{q}_l$  contracted with some  $a_i a_k a_l$ , only if this piece is there and if  $U$  is only a function of the coordinates not of the velocities, then our  $H$  becomes  $T^2$  plus  $U$  and we saw that this is what was equal to the total energy of the system.

So, let us say you have such a system where the Hamiltonian can be identified with total energy and then the above relation  $dH$  over  $dT$  is equal to 0, if that holds true would imply that total energy is conserved. Let us take a quick simple example of a harmonic oscillator and if you recall the Lagrangian is simply half  $m \dot{x}^2$  minus half  $k x^2$ .

So, if you now do a Legendre transformation then you know that the Hamiltonian will be  $p \dot{x}$  minus  $L$  and then you have your Lagrangian which is half  $m \dot{x}^2$  minus half  $k x^2$  and you also recall that your  $\frac{\partial L}{\partial \dot{x}}$  is what is  $p$  which if you take the derivative you get  $m \dot{x}$  which you can solve to write  $\dot{x}$  to be  $p$  over  $m$  and your  $(\dot{x})^2$  square I think I am there is no square here.

So, that is fine and where were we, so with this I can write the Hamiltonian to be  $\frac{p^2}{2m}$  plus half  $k x^2$ . So, that is the Hamiltonian and which you already knew because this is the total energy for the system. And the system is conservative it depends only, and the potential energy depends only on  $q$ , only on the  $x$  and this is anyway just has the quadratic piece in velocities, so you expect that the Hamiltonian will come out to be this.

And because this Lagrangian does not depend explicitly on time, remember the coordinates depend on  $T$  but that is that time dependence is implicit through the coordinates, but there is no explicit time dependence in here so partial derivative of  $H$  with respect to  $T$  is vanishing and which implies that the total derivative will also vanish with time, which is just that the total energy is conserved which you already know for harmonic oscillator which means that your  $H$  will be a constant.

So, let us call it  $E$  that constant energy and which implies that these piece is  $\frac{p^2}{2m}$  plus half  $k x^2$  they will be equal to some constant  $E$  and if I divide by energy on both sides I get this that is good. Now, we can ask how things look like in phase space, you remember we introduce phase space, let me go back.

(Refer Slide Time: 14:40)

- $p$  &  $q$  are treated equally
- 2<sup>nd</sup> first order differential equations

Lagrangian  $(q_1, \dots, q_n) \in$  Configuration space

Hamiltonian  $(q_1, \dots, q_n, p_1, \dots, p_n) \in$  Phase Space  
2<sup>nd</sup> dim

This was the two n-dimensional space in which you have access to be  $q_1$   $q_2$  so and so forth and  $p_1$   $p_2$  and so forth.

(Refer Slide Time: 14:55)

1D harmonic oscillator  
Phase space 2d

$\frac{p^2}{2m} + \frac{kx^2}{2} = E$

$m, k \gg 1$

$p^2 + m^2 = 2E/$

system at any time  $t$  will be represented by  
a point in the phase space.

So, for harmonic oscillator 1 dimensional harmonic oscillator which we have just looked at the phase space is how many dimensions? Phase space is two dimensional, one for  $q$  and one  $p$ , so you have your let us say here  $q$  and  $p$  or maybe I think I called  $x$  and  $p$ , so let me write  $x$ . Now, we have the equation as  $p$  square over  $2mE$  plus  $k$  over  $2E$   $x$  square is equal to 1, this is what I think we had.

Now, if you are given one oscillator and then for that oscillator this is the condition that has to be satisfied, so if you look at what this represents, it represents an ellipse in the  $xp$  plane but for simplicity let me put all the constants  $m$  and  $k$  to be 1 then you just have circles. So, you have  $p^2 + x^2 = 2E$ .

So, you get concentric circles and radius of the circle depends on your total energy of the system, treat them as circles, treat them as circles these are not very circular things which I am drawing, let me draw again, so you have 1 circle here which corresponds to some energy response this  $(17:15)$  responds to a little higher energy, so your system depending on how much total initial energy has been given to it, it will be moving along one of these circles.

So, your entire system is denoted by one point, at a given time it will be somewhere and as time changes that point is going to move. I hope that is clear because if you specify the coordinates at a given time all the coordinates, in this case it is only one and all the momenta and then that represents one point in your  $2n$ -dimensional space.

So, your system is going to be represented by a single point in phase space, let me write this down anyway, so system at any time  $t$  will be represented by a point in the phase space. That is clear. So, now as time changes that point is going to move with time, so that point is going to flow. And what I have drawn here as these circles is that if you have your energy such that your point is here then it is going to move along this circle for this one dimensional harmonic oscillator.

And if your energy was different and it was such that it is here and it is going to move on this circle. So, that is what our phase space will look like the trajectories of this point or the system will look like in the phase space that is good. Now, I am going to prove a very nice theorem and the theorem is the following, actually before I say the theorem let us ask the following.

(Refer Slide Time: 19:46)

A system with  $2n$  dim phase space

LIUVILLE'S Theorem.

$$\vec{z} = \{q_1, q_2, \dots, q_n, p_1, p_2, \dots, p_n\}$$

$$\dot{q}_k = \frac{\partial H}{\partial p_k}, \quad \dot{p}_k = -\frac{\partial H}{\partial q_k}$$

$$\vec{f} = \left\{ \frac{\partial H}{\partial p_1}, \frac{\partial H}{\partial p_2}, \dots, \frac{\partial H}{\partial p_n}, \frac{\partial H}{\partial q_1}, \dots, -\frac{\partial H}{\partial q_n} \right\}$$

$$\rightarrow \frac{d\vec{z}}{dt} = \vec{f}(\vec{z})$$

$$\rightarrow \vec{z}(t_0 + dt) = \vec{z}(t_0) + \vec{f}(\vec{z}(t_0))dt + O(dt^2)$$

Volume at  $t_0$ :  $d^{2n}x(t_0) = dx_1 dx_2 \dots dx_{2n}$

$t_0 + dt$ :  $d^{2n}x(t_0 + dt) = dx_1(t_0 + dt) \dots dx_{2n}(t_0 + dt)$

So, let us say I have some let us say we are given a system with two n-dimensional phase space, meaning it has n generalize coordinates and correspondingly and generalized momenta and the particle and this the system will be denoted by a point in that phase space by a point in the phase space, so I do not wish to draw when I cannot not that I wish but I cannot draw a two n-dimensional space but I can draw two dimensional space, so I am going to draw it like this.

So, you can imagine that q stands for all these coordinates, you can think that this is a two dimensions two n-dimensional space, so you have all  $q_1, q_2$  and  $q_n$  in here perpendicular to all these and similarly  $p_1, p_2$  and so forth all these coordinates are here. An imagined a patch a region, so a region not a patch because I am thinking of two n-dimensions, so imagine a region, here and this is going to occupy some volume, so just to give it a little bit of 3 dimensional look or whatever, now let me draw this curly line, so you imagine it, it encloses some volume.

So, right now I am not trying to even make a any connection with system or whatever, your system is given, so each point corresponds to one system, but forget about all that, that how many systems are there and all these questions just look this as a geometrical problem, we are given some volume enclosed by this, so the region let us call it I think I want to call it some or something whatever and we also tell the equations of motion.

So, each point here is going to evolve in time according to the Hamilton's equations of motion. So, it is going to go somewhere as time goes on and what we want to ask is if I start with some

volume here, so if I look at all these points, all these points are going to move in time and goes to somewhere else and I want to ask how this volume is going to change with time.

So, if I wait for some time and after a while if this initial volume enclosed here was  $V_0$  or  $V$  at time  $t_0$  what it becomes after some time has passed, that is what we want to ask, let us say it becomes like this. So, I am not saying the shape will be similar or same, shape changes and we want to know whether it has increased or decreased or what has happened at a different time  $t$ , so you go from  $t_0$  to  $t$  and this is what we want to ask.

And what we are really looking at now is what is called Liouville's theorem I will tell you at the end what the theorem is, Liouville's theorem. So, I hope the question is clear and let me just create some notation. So, I want to define this entire set of coordinates  $q_1, q_2$  so and so forth  $q_n$  and then you have  $p_1, p_2$  as  $p_n$  so you have all the  $2n$  coordinates here, let me call these collectively as  $x$  and I put a vector as  $x$  just to mean all these that it is a multi-component thing.

And then also I have my Hamilton's equations which let me write down  $\dot{q}_k$  is  $\frac{\delta H}{\delta p_k}$  and you have  $\dot{p}_k$  as  $-\frac{\delta H}{\delta q_k}$  and if I am differentiating  $H$  with  $q$  I remember that there is a minus sign here. So, I define a vector  $f$  to be the following, so  $\frac{\delta H}{\delta p_1}, \frac{\delta H}{\delta p_2}$  so and so forth,  $\frac{\delta H}{\delta p_n}$ , then you have  $\frac{\delta H}{\delta q_1}$  with the minus sign, so I am what I am doing is I am just listing these right hand side parts here and here along this.

And you go further and  $\frac{\delta H}{\delta q_n}$  again there is a minus sign I put here, this entire set of quantities I denote by vector  $f$ . So, these equations of motion Hamilton's equations of motion here using the notation which we have written down just now can be written as  $\dot{x}$  is equal to  $f$ . So, if I look at for example what is  $\dot{x}_1$  it will be  $f_1$  which is  $\frac{\delta H}{\delta p_1}$ .

And what is  $\dot{x}_1$ ? It is  $\dot{q}_1$ , so  $\dot{q}_1$  should be  $\frac{\delta H}{\delta p_1}$  which is correct, which is what you have it here and let us look at this one this is let us say  $x_{n+1}$ ,  $x_{n+1}$  would be  $p_1$  and  $\dot{p}_1$  should be  $f_{n+1}$  which is  $-\frac{\delta H}{\delta q_1}$  which is correct. So, all I have done is written down Hamilton's equation in this form beyond that I have not done, there is no content in here it is just notation.

So, these are our  $2n$  first order differential equations in time and then I can write  $x$  at any time I mean at time  $t$  naught plus  $dt$ , so I am starting with time  $t$  naught and I look at what happens at after small interval of time  $dt$  and you can write down this as  $x$  of  $t$  naught plus  $f$  of  $x$  at  $t$  naught times that small time interval  $dt$  and then you will have all the higher order corrections, this is just this equation written or solved near  $t$  naught, that is fine that is good.

So, what is contained in here is the information about how the points are going to move in time, that is what is contained in here which is same as this equation. Now, let us first before we are able to ask how things how the volume is going to change with time I should first write down the expression of the volume and write down how volume changes.

So, the volume is the following so let me here it write down here itself, so volume at, volume at  $t$  naught is what is  $d^2x_n$  at  $t$  naught, which is nothing but  $dx_1$ , I am dropping the  $t$  naught now  $dx_2$ , so and so forth,  $dx_{2n}$ , which is just  $dq_1$   $dq_2$  up to  $dq_n$  and then  $dp_1$   $dp_2$  up to  $dp_n$ , that is what the volume is at time  $t_0$ , you can put  $t_0$  here as the arguments.

And then at time  $t$  naught plus  $dt$  you will have  $d^2x_n$  of  $t$  naught plus  $dt$  which is again the same thing, similar thing  $dx_{2n}$   $t$  naught plus  $dt$ . So, that is fine, that is that was easy. Now, how are the two volumes related this one and this one? You know how they are related and the relation is this you take you go let me just show here, you see the  $x$  is going to change like this, so you have a transformation of your  $x$  from this to this one which is given by this relation. So, all you have to do is find the Jacobian of transformation.

(Refer Slide Time: 30:37)

J = Jacobian:

$$dx^{2n}(t_0+dt) = J dx^{2n}(t_0)$$

where  $J = \det \left( \frac{\partial x_k(t_0+dt)}{\partial x_m(t_0)} \right)$

2n component form

$$x_k(t_0+dt) = x_k(t_0) + f_k(x(t_0)) dt + G(dt^2)$$

$$\frac{\partial x_k(t_0+dt)}{\partial x_m(t_0)} = \delta_{km} + \frac{\partial f_k}{\partial x_m} dt + O(dt^2)$$

RHS =  $\mathbb{1} + A dt + O(dt^2)$

$\det(\mathbb{1} + A dt)$

A system with 2n dim phase space

LIUVILLE'S Theorem.

$$\vec{z} = \{q_1, q_2, \dots, q_n, p_1, p_2, \dots, p_n\}$$

$$\dot{q}_k = \frac{\partial H}{\partial p_k}, \quad \dot{p}_k = -\frac{\partial H}{\partial q_k} \leftarrow$$

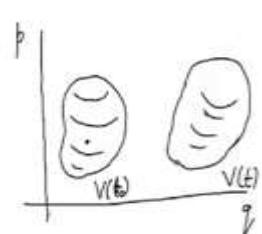

$$\vec{f} = \left\{ \frac{\partial H}{\partial p_1}, \frac{\partial H}{\partial p_2}, \dots, \frac{\partial H}{\partial p_n}, \frac{\partial H}{\partial q_1}, \dots, \frac{\partial H}{\partial q_n} \right\}$$

$\rightarrow \dot{\vec{z}} = \vec{f}(\vec{z}) \rightarrow$

$$\rightarrow \vec{z}(t_0+dt) = \vec{z}(t_0) + \vec{f}(\vec{z}(t_0)) dt + G(dt^2) \leftarrow$$

Volume at  $t_0$ :  $d^{2n}x(t_0) = dx_1 dx_2 \dots dx_{2n} \checkmark$

$t_0+dt$ :  $d^{2n}x(t_0+dt) = dx_1(t_0+dt) \dots dx_{2n}(t_0+dt) \checkmark$

So, all you have to do is find the Jacobian and let us denote Jacobian by J, then you know that the two volumes are related by the following  $dx^{2n}$  at  $t_0 + dt$  is equal to  $dx^{2n}$  at  $t_0$  and the change is this, it is you have a factor of the Jacobian which comes in here and if you recall where the Jacobian is just the determinant of this matrix  $dx^{2n}$  at  $t_0 + dt$  over  $dx^{2n}$  at  $t_0$ , so you have to just take these you have to construct the matrix which contains all these partial derivatives.

So and k runs from 1 to 2n and also runs from 1 to 2n, so this is 2n cross 2n-dimensional matrix and you have to find the determinant of this and then multiply it here which gives you the

new volume. So, now the task is to evaluate the Jacobian, the moment I know the Jacobian I know the answer and I will have to just integrate over that entire region to generate the volume, right now these are differential elements of the volume, so let me do that, let me try to evaluate the Jacobian and of course to do that you have to use this piece of information that which knows how things are changing with time.

So, let me write this equation here this vector equation  $\mathbf{x}$  as  $\mathbf{x}(t) + \mathbf{f} \, dt$  in the component form. So, in component form you have  $x_k(t) + dt$  is equal to  $x_k(t) + f_{km} x_m(t) dt$  and you have higher order terms also which anyway we are going to drop because we are looking at infinitesimal  $dt$  I can drop it here itself it is unnecessary to carry this.

So, let us calculate this derivative  $\frac{\partial x_k}{\partial x_m}$ , clearly this will give you  $\delta_{km}$  unless  $k$  is equal to  $n$  this guy is 0 only when  $k=m$  are equal this is going to give you  $1 + \frac{\partial f_{km}}{\partial x_m}$ , so  $\frac{\partial f_{km}}{\partial x_m}$ , I will drop this  $x(t)$  for ease of writing and clarity but it is there that argument is there and you have a  $dt$  here, let me keep writing this.

Now, what you have if I want to write the same thing using matrix notation then the right hand side this side you can write as identity matrix plus let me think I want to put  $dt$  here I am that is correct, let me denote this matrix by matrix  $A$ , so the matrix  $A$  has as its components  $\frac{\partial f_{km}}{\partial x_m}$  times  $dt$  you have and you have other order  $dt^2$  terms.

So, what we want to do is look at the determinant of this, so we are interested in finding out the determinant of  $1 + A \, dt$  and we are we want the result only up to  $dt$ , we are not interested in higher-order contributions. Now, that is easy, actually that is not very difficult, all you need to do is there are many ways in which you can do this, but you can use the following formula which you should be familiar with.

(Refer Slide Time: 35:24)

$$\begin{aligned}
 \det a &= \epsilon_{i_1 i_2 \dots i_n} a_{i_1 1} a_{i_2 2} \dots a_{i_n n} & \epsilon_{123 \dots n} &= +1 \\
 J &= \epsilon_{i_1 i_2 \dots i_n} (\delta_{i_1 1} + A_{i_1 1} dt) \dots (\delta_{i_n n} + A_{i_n n} dt) \\
 &= \epsilon_{i_1 i_2 \dots i_n} + \epsilon_{i_1 i_2 \dots i_n} A_{i_1 1} dt \cdot \delta_{i_2 2} \dots \delta_{i_n n} \\
 &\quad + \epsilon_{i_1 i_2 \dots i_n} A_{i_2 2} dt \cdot \delta_{i_1 1} \dots \delta_{i_n n} \\
 &\quad + \dots + \epsilon_{i_1 i_2 \dots i_n} A_{i_n n} dt \cdot \delta_{i_1 1} \dots \delta_{i_{n-1} n-1} \\
 &\quad + G(dt^2) \\
 &= 1 + \epsilon_{i_1 i_2 \dots i_n} A_{i_1 1} dt + \dots + \epsilon_{i_1 i_2 \dots i_n} A_{i_n n} dt + G(dt^2) \\
 &= 1 + \text{tr} A \cdot dt + G(dt^2) = 1 + \vec{\nabla} \cdot \vec{f} dt + \text{higher order}
 \end{aligned}$$

Let us say you have a as A matrix, then the determinant of that matrix can be written as epsilon i1 i2 in times ai11 ai1 i22 ain n. So, that is the result and you know the Levi-Civita tensor is or this and total in the symmetric matrix is 1 if you have i this is so epsilon 1 2 3 so and so forth n is defined to be plus 1 and whenever you interchange any two indices you pick up a minus sign that is how this option is defined and ai11 these are the matrix elements of the matrix A.

So, that is what I am going to use here. So, let us see what my jacobian is now, my J is epsilon i1 i2 and it will go up to 2n because you have two n-dimensional 2n cross 2n dimension matrix and then here you have your 1 plus A dt, so in component form this becomes a1 the first sorry corresponding to this you have to write delta i11 plus capital Ai11 dt that is what you will have here and then you have all those factors and for this last one you will have delta i2n2n plus Ai2n2n dt

Now, let us collect terms of order I mean the terms which are not proportional to dt and then the terms which are proportional to dt and then we will drop the terms which are higher powers in dt that is what I am going to do. So, the terms which do not involve any dt are going to come from multiplying this epsilon with the deltas without involving any of the As.

So, if you have this epsilon multiplying all the deltas these deltas will force the i but this delta will force the i1 to be 1 in here, so it will become epsilon 1, then i2 will be forced to 2, so it will

become  $\epsilon_{12}$  and similarly this thing will be force  $i_2$  into be  $2n$ , so one term you are going to get is  $\epsilon_{1n}$  so forth up to  $2n$ , so that is the term without any  $dt$  plus now you are going to generate the terms proportional to  $dt$  in many ways.

So, if you pick up this factor from this term and all the others are deltas then you are going to have a term proportional to  $dt$ . Similarly, if you pick from this one a delta and you pick  $a_{21}$   $a_{22}$  and all others to be delta then you get another term which is proportional to  $dt$ , so let me write that down, so you are going to generate terms like this, let us reduce some labour in writing, so you are going to get  $A_{i1} dt$  and all the others will be just delta.

So, you will have delta I am just writing  $\delta_{i1}$  also, but it is not there I will just strike it off,  $i_{22}$  and similarly you proceed and go up to  $i_{2n}$  and this factor is missing in this one. And these kind of terms let me if I was a bit more careful I could have, so I will just pull out this term because you see now you understand you are going to the next term which I am going to write will again have an epsilon it will have a corresponding  $A$  times  $dt$  and the same piece with this being removed and you will keep this maybe let me I should let me write down.

Plus  $\epsilon_{i1}$   $i_{2n}$  and then you will have  $A_{i2n} dt$  and all these deltas,  $i$  subscript  $2n$ , so this time, and the last term this will be gone and the all the other terms that you are going to generate will involve multiplication of at least two pieces of  $A$ s which will bring with them at least a second power of  $dt$ , so we are going to drop all those, so this is not there, so all those other terms will be higher orders in the change in time.

And now that is easy your first term is just one which you also expect because to the lowest order there is no change right because the time you are looking at the volume change after and infinite decimal time, so you expect that Jacobian would be to the lowest order 1, so that is correct, that is good, you have got of the 1 here plus we expect something proportional to  $dt$  and let us look at here, these all these deltas will force all the except for  $i_1$  all the other indices to be equal to what you have here.

So, you will have  $\epsilon_{i1}$   $2$   $3$   $4$  up to  $2n$  and then you have  $A_{i1} dt$ , so you will get let me write down  $\epsilon_{i1}$   $2$ , sorry not  $2$ ,  $2$   $3$  so forth to  $2n$  with  $A_{i1} dt$  and all such terms are here let me I down anyway, epsilon this will be  $1$   $2$  so forth up to  $2n$  minus 1 and then you will have  $i$  subscript  $2n$  and you will have  $A_{i2n} dt$ , plus higher order terms.

Now, you see if this will be non-zero only if  $i_1$  is 1, if  $i_1$  is 2 or 3 or something it is going to be 0 and you have a summation over  $i_1$  because it is summation convention is still here, so the only possibility for this is to be 1 and that will give you a positive sign because this will be fine epsilon 123 and that will force this one to be  $A_{11}$ .

So, it is 1 plus this will be  $A_{11} dt$ , next one will be  $A_{22} dt$  and similarly  $A_{2n2n} dt$ . So, you have trace of  $A$  times  $dt$ , the sum of all the diagonal entries is the trace of this matrix.  $A$ . That is good, now this is just 1 plus let me write down now you remember your capital  $A$  was the matrix this one this matrix, now we are looking at the trace of this so you have  $\delta f_k$  over  $\delta x_k$  and you have a summation over  $k$  which is just gradient of sorry divergence of  $f$ .

So, I can write as divergence of  $f$ , remember divergence is  $\text{del } f$  by  $\text{del } x_1$  plus  $\text{del } f$  by  $\text{del } x_2$  which is just what is appearing as traces for you here. And  $dt$  is still there plus higher order.

(Refer Slide Time: 45:18)

$$\begin{aligned} d^{2k} x(t_0 + dt) &= \underbrace{(1 + \nabla \cdot f dt)}_{\text{trace of } A} d^{2k} x(t_0) \\ V(t_0 + dt) &= \int d^{2k} x(t_0 + dt) \\ &= \int d^{2k} x(t_0) \cdot (1 + \nabla \cdot f dt) \\ \lim_{dt \rightarrow 0} \frac{V(t_0 + dt) - V(t_0)}{dt} &= \int d^{2k} x(t_0) (\nabla \cdot f) \\ \left. \frac{dV}{dt} \right|_{t=t_0} &= \int \nabla \cdot f d^{2k} x(t_0) \\ \text{if } \nabla \cdot f &= 0 \quad \left. \frac{dV}{dt} \right|_{t_0} = 0 \end{aligned}$$

A system with  $2n$  dim phase space.

LIUVILLE'S Theorem:

$$\vec{r} = \{q_1, q_2, \dots, q_n, p_1, p_2, \dots, p_n\}$$

$$\dot{q}_k = \frac{\partial H}{\partial p_k}, \quad \dot{p}_k = -\frac{\partial H}{\partial q_k} \leftarrow$$

$$\vec{f} = \left\{ \frac{\partial H}{\partial p_1}, \frac{\partial H}{\partial p_2}, \dots, \frac{\partial H}{\partial p_n}, \frac{\partial H}{\partial q_1}, \dots, -\frac{\partial H}{\partial q_n} \right\}$$

$$\rightarrow \dot{\vec{r}} = \vec{f}(\vec{r}) \rightarrow$$

$$\rightarrow \vec{r}(t_0 + dt) = \vec{r}(t_0) + \vec{f}(\vec{r}(t_0)) dt + O(dt^2) \leftarrow$$

Volume at  $t_0$ :  $d^{2n}x(t_0) = dx_1 dx_2 \dots dx_{2n} \checkmark$

$t_0 + dt$ :  $d^{2n}x(t_0 + dt) = dx_1(t_0 + dt) \dots dx_{2n}(t_0 + dt) \checkmark$

So, we are almost there we have shown that if you look at the differential volume element in this  $2n$  dimensional space sorry  $t$  naught plus  $dt$  then it becomes  $1$  plus divergence of  $f$   $dt$ , I am going to drop now all the higher-order pieces, that is how you transform. So, that is what your Jacobian is, this is your Jacobian. Now, let us look at the volume, so volume at  $t$  naught plus  $dt$  it is just obtained by integrating all the differential volume element and this as you have determined is just  $d^{2n}x$  and then  $d^{2n}x$  at  $t$  naught and then you have your Jacobian which is  $1$  plus divergence of  $f$  times  $dt$ .

So, let me split it into two integrals, so one will have this one multiplied in here and this will give you the volume at time  $t$  naught, let me take it to the left hand side, it will have a minus sign then and then the second term will be proportional to  $dt$ , so if I divide by the time  $dt$  I should have written  $\Delta T$  it would have made more sense, so anyhow, so you have let me call it to make it look more appropriate, so that is what I have.

So, instead of  $dt$  let us put  $\Delta t$  and then put  $\Delta t$  to the left and take that limit. Then this will be only this piece remains here, so you have the integral over the volume element of divergence of  $f$ . So,  $dV$  over  $dt$  evaluated at time  $t$  equal to  $t$  naught is integral divergence of  $f$  times  $d^{2n}x$   $t_0$ . Now, if so happens that your  $f$  which you define here, where is it? Yes, these  $f$ , which are on the right hand side of the differential equation, then if it so happens that the  $f$  which you have here is divergence less, so let us say I assume that divergence of  $f$  is equal to  $0$ .

If that is true, then  $dV$  over  $dt$  at any time  $t$  naught will be 0, or at  $(0)$ (48:33) all times  $t$  naught at all times will be 0, so the volume is not going to change with time if your  $f$  was divergence less. So, that is the generic conclusion for any system of ordinary differential equations but now let us look at what we have for our specific case of Hamilton's equations. So, let us see what we have for divergence of  $f$ .

(Refer Slide Time: 49:01)

$\nabla \cdot f$  for Hamilton's eq'n.

$$\nabla \cdot f = \frac{\partial}{\partial q_1} \frac{\partial H}{\partial p_1} + \dots + \frac{\partial}{\partial p_n} \frac{\partial H}{\partial p_n}$$

$$= \frac{\partial}{\partial p_1} \frac{\partial H}{\partial q_1} - \dots - \frac{\partial}{\partial q_n} \frac{\partial H}{\partial p_n}$$

$$= 0$$

$\frac{dV}{dt} = 0$  ;  $\frac{\partial V}{\partial t} = 0$

Volume remains unchanged with time.

Liouville's theorem.

A system with  $2n$  dim phase space

LIUVILLE'S Theorem.

$$\vec{z} = \{q_1, q_2, \dots, q_n, p_1, p_2, \dots, p_n\}$$

$$\dot{q}_k = \frac{\partial H}{\partial p_k} \quad ; \quad \dot{p}_k = -\frac{\partial H}{\partial q_k} \quad \leftarrow$$

$$\vec{f} = \left\{ \frac{\partial H}{\partial p_1}, \frac{\partial H}{\partial p_2}, \dots, \frac{\partial H}{\partial p_n}, \frac{\partial H}{\partial q_1}, \dots, -\frac{\partial H}{\partial q_n} \right\}$$

$$\rightarrow \frac{d\vec{z}}{dt} = \vec{f}(\vec{z}) \quad \leftarrow$$

$$\rightarrow \vec{z}(t_0 + dt) = \vec{z}(t_0) + \vec{f}(\vec{z}(t_0)) dt + O(dt^2) \quad \leftarrow$$

Volume at  $t_0$  :  $d^{2n}x(t_0) = dx_1 dx_2 \dots dx_{2n} \quad \leftarrow$

$t_0 + dt$  :  $d^{2n}x(t_0 + dt) = dx_1(t_0 + dt) \dots dx_{2n}(t_0 + dt) \quad \leftarrow$

So, divergence of  $f$  for Hamilton's equations, let us see, so your divergence of  $f$  is, let us recall,  $\frac{\partial}{\partial q_1} \frac{\partial H}{\partial p_1}$  that is first coordinate and then recall what  $\nabla \cdot f$  sorry  $f$  was,  $f$  was your, where is it?  $\frac{\partial H}{\partial p_1}$ , let us write it here. Similarly, you keep on going up to  $q_n$  and you

have  $\frac{\delta H}{\delta p_n}$ , then you have more terms  $\frac{\delta}{\delta p_1}$  and let us recall what is  $f_{n+1}$  was,  $f_{n+1}$  was minus  $\frac{\delta H}{\delta q_1}$ .

So, you have instead of a plus here a minus  $\frac{\delta H}{\delta q_1}$  and then you continue and  $\frac{\delta}{\delta p_1}$  and  $\frac{\delta H}{\delta q_n}$ , that is all you have. So, this is  $H$  is being differentiated with respect to  $q_1$  and  $p_1$  and here also the same thing and the order does not matter and is the relative sign, so these two will give you 0, similarly all the other terms will also cancel pairwise and will leave you 0, so indeed for our Hamilton's equation we have divergence equal to 0 which means that whatever volume you take in the phase space it is going to evolve with time in such a manner that this time derivative is 0, meaning the volume is going to remain unchanged, remains unchanged with time.

The shape of the volume may change, it will change in general, but the volume contained all the points which move the volume which they are going to span out it will still be the same as the original volume and this is what is Liouville's theorem, that is nice cheering which is very useful in statistical mechanics when you talk about different and symbols, but here we will not even worried about defining and symbol there is no need in here.

But this is a very useful theorem which you will use for example in statistical mechanics, I think this is all that I wanted to say here I know that I can make a remark, I hope this is clear that this is the total time derivative of volume and you should contrast it with the partial time derivative. This statement where the partial time derivative is 0 is different from the total time derivative.

So, when you are talking about a total time derivative in addition to time changing the coordinates are also changing, because  $\frac{d}{dt}$  is partial derivative with time plus derivatives with respect to all the other coordinates, so you are really moving together with all those points as they move and you are then asking about the volume whether it changes or not.

But if you are just looking at this partial derivative, then you are staying put at one place and you are just looking at the time changing, as time passes and then of course the volume will be changing there it will be reducing for example. So, what happens there locally is different from what happens when you are flowing with the points. So, we are talking about this piece, we are not talking about just time passing at the same place. Anyhow, so this is the Liouville's theorem which is quite useful and let us meet in the next video too carry this subject further.
