Hamiltonian Mechanics: Generating functions of the 4 kinds

(Refer Slide Time: 00:14)

CANONICAL TRANSFORMATIONS cont...

$$dF = p dq - P dQ + (H' - H) dt$$

■ $F_1(q, \alpha) :$

$$p_k = \frac{\partial F_1(q, \alpha)}{\partial q_k} ; -P_k = \frac{\partial F_1(q, \alpha)}{\partial \alpha_k} ; H' = H + \frac{\partial F_1}{\partial t}$$

$$dF = \sum_k p_k dq_k - (d(P_k \alpha_k) - \alpha_k dP_k) + (H' - H) dt \quad d(P_k \alpha_k) = P_k d\alpha_k + \alpha_k dP_k$$

$$d(F + \sum_k P_k \alpha_k) = \sum_k p_k dq_k + \sum_k \alpha_k dP_k + (H' - H) dt$$

" $F_2(q, P)$

$$dF_2 = \sum_k \frac{\partial F_2}{\partial q_k} dq_k + \sum_k \frac{\partial F_2}{\partial P_k} dP_k + \frac{\partial F_2}{\partial t} dt$$

Example: $F(q, \alpha) = q\alpha$

$$\left. \begin{aligned} p &= \frac{\partial F}{\partial q} = \alpha \\ -P &= \frac{\partial F}{\partial \alpha} = q \end{aligned} \right\} \rightarrow \begin{aligned} \alpha &= p \\ P &= -q \end{aligned}$$

÷

$$\underline{q, p} : \quad p = f(q, P) = f(q, p(q, P))$$

$$g(q, \alpha, p) = 0$$

$q, p \rightarrow q, \alpha$ as independent

$$dF(q, \alpha) = \frac{\partial F}{\partial q_k} dq_k + \frac{\partial F}{\partial \alpha_k} d\alpha_k + \frac{\partial F}{\partial t} dt \quad (2)$$

$$p_k = \frac{\partial F}{\partial q_k}$$

$$-P_k = \frac{\partial F}{\partial \alpha_k}$$

$$H'(q, p, t) = H(q, p, t) + \frac{\partial F}{\partial t}$$

$$H(q, p, t)$$

↓

$$H(q(q, P), p(q, P), t)$$

In the last video, we wrote down the Total Differential of the Generating Function, which is going to generate transformations of the coordinates, canonical coordinates, and which was of this form. Let me write here. $dF = p dq - P dQ$ and then we had, and then we had H' prime minus $H dt$. I am going to use this one again and again. And I also argued that we can treat F as a function of small q and capital Q .

So, F , we said that we will treat as a function of independent variables q and capital Q . If I do so, then I generate a set of transformations and I will label F with a subscript 1 in this case, if when I make the choice that I have a q , old q and the new Q here. And we saw that here, let us go back, that these are the relations which, see the small p and capital P are given by this. So, both are derivative with respect to, good, so let us write this down here.

If this choice is made, then we saw that we have $\frac{\delta F_1}{\delta q}$. Let me emphasize this. And this gave us p . And then the next was capital P , was $\frac{\delta F_1}{\delta Q}$, and here we had small q and capital Q and I believe there was a minus sign. Let us go back. Let us correct. And the third was that, my H' prime is H plus $\frac{\delta F_1}{\delta t}$. So, you can put the indices, I want to put it in.

And we also saw an example of the generating function, and we saw that this was just interchange interchanging what we call coordinates and what we call momenta. Now, let us proceed further. So, let us start again with this expression of the generating function. And now, I want to, let us see, I will take this term $P dQ$ and instead of having a differential dQ , I will turn it into a differential of dP . So, all you need to use is that a differential of P times Q will be $P dQ$ plus $Q dP$.

If you do so, then our expression can be written as this, pdq and you have minus, let's put a minus here, our PdQ is d of pQ minus QdP . So, now I will have a dP instead of a dQ as was the case before and then of course, this term. Now, this total derivative term, total differential term, I can bring to the left and write d of F minus PQ , let me not forget that I have to put these indices and the summation is implied, $P_k Q_k$, and this will be equal to $p_k dq_k$, this term is here, this term I have taken, there is a sign issue. Let us see.

So, my PdQ , it looks fine, what has gone wrong? Let us proceed, let us see. I do not see a mistake right now. Minus PdQ minus dPQ is PdQ plus QdP . And I have a PdQ which will make it, this looks correct. So, maybe I made a mistake while writing my note. Anyway, so, dF and there will be a plus here because this guy goes to that side is equal to $p_k dq_k$, that is correct. And then we have a plus $Q_k dP_k$ plus H' prime minus $H dt$.

Now, you see, I have turned this total differential and on the right hand side, you see the differential involved are the Q_k and the capital P_k . So, I define a new function F of 2 to be this quantity in the, in the brackets. So, with this, I can write it as F_2 . And F_2 will be a function of q and P , so q , small q and capital P . So, I get dF_2 is equal to this quantity. And because it is a function of q and P , I can write it as, I mean generally, generically, I can write that the $dq_k dq_k$ plus $\frac{\partial F_2}{\partial P_k} dP_k$ plus if there are any time derivatives, it will have this part, this term also. Now, if you compare these 2, you will get the $\frac{\partial F_2}{\partial q_k}$ as p_k .

(Refer Slide Time: 09:02)

$$F_2(q, P): \quad p_k = \frac{\partial F_2(q, P)}{\partial q_k}, \quad Q_k = \frac{\partial F_2(q, P)}{\partial P_k}; \quad H' = H + \frac{\partial F_2}{\partial t}$$

$$\begin{aligned} dF &= pdq - PdQ + (H' - H)dt \\ &= d(pq) - qdp - PdQ + (H' - H)dt \\ d(F - pq) &\equiv dF_3(p, Q) = -qdp - PdQ + (H' - H)dt \\ dF_3(p, Q) &= \frac{\partial F_3}{\partial p} dp + \frac{\partial F_3}{\partial Q} dQ + \frac{\partial F_3}{\partial t} dt \end{aligned}$$

$$F_3: \quad -q = \frac{\partial F_3(p, Q)}{\partial p}; \quad -P = \frac{\partial F_3(p, Q)}{\partial Q}; \quad H' = H + \frac{\partial F_3}{\partial t}$$

So, we get $\frac{\delta F_2}{\delta q}$ as, let us check, no, $\frac{\delta F_2}{\delta P}$. What happened? And $\frac{\delta F_2}{\delta P}$ is equal to q . And I should emphasize here, that these are functions of small q and capital P . And as before, H' is H plus $\frac{\delta F_2}{\delta t}$. $\frac{\delta F_2}{\delta P}$, that is q , all looks good to me. So, this is for F_2 . And our F_2 is a function of q and P . So, this is the second kind of generating function, which involves the function, generating function to be a function of old q and new P , and the first kind involved generative function of old q and new Q .

These are 2 different, they are defunctions. We can again go back and, go back to the original equation here and make a different choice of variables for F . So, let me do that now. This will be a the third. Now, what I do is, I write my, let me write dF again, Pdq minus capital PdQ plus H' minus $H dt$. And this time what I will do is, I will look at the first term here, first differential and write it as $d(pq)$. So, this gives $d(pq)$ plus qdp . So, I should subtract from this qdp and then you have the remaining terms.

And I will now, as before, take this total (deri) differential to the left hand side and combine with F and I get dF minus qdp , small p small q . Let us see here. And you can supply the indices here, the case, but I will omit right now. So, this you get to be, this we will define as dF_3 of what will, what will be the variables? Variables will be the small p and capital q , because this is gone to the left. So, let me write, small p and capital Q . So, your F_3 is this.

And what is dF_3 , dF_3 is minus qdp and minus PdQ plus H' minus $H dt$. And as before, I can write my total differential of dF_3 , which is a function of small p and capital Q as $\frac{\delta F_3}{\delta p} dp$ plus $\frac{\delta F_3}{\delta Q} dQ$ plus $\frac{\delta F_3}{\delta t} dt$. And if I compare the coefficients of dp and dQ and dt , I conclude that $\frac{\delta F_3}{\delta p}$ is minus q . And $\frac{\delta F_3}{\delta Q}$, again I should emphasize that these are now functions of small p and q over Q is minus p , the new p . And your H' is same as H plus a total derivative term of F_3 .

And if your F_3 does not depend explicitly on time, then H' is same as H , expressed in new coordinates. So, let us put the indices. And let me see if it is correct. Minus qk , that is good, minus p $\frac{\delta F_3}{\delta Q}$, that is also good. So, this is the case for your F_3 . So, this is your third kind of generating function. And now, I will do for one more case. Let me first put a box in here.

So, final fourth variety, let us go here, I will have to now change both the, let me go here, now I will take this dF and change from dq to dp and here from capital dQ to capital dP, that is what I will do.

(Refer Slide Time: 16:08)

$$dF = d(pq) - q dp - (d(PQ) - Q dP) + (H' - H) dt$$

$$d(F - \sum_k p_k q_k + \sum_k P_k Q_k) = -q dp + \alpha_k dP_k + (H' - H) dt$$

$$dF_4(p, P) = \frac{\partial F_4}{\partial p} dp + \frac{\partial F_4}{\partial P} dP + \frac{\partial F_4}{\partial t} dt$$

$$F_4(p, P): \quad -q_k = \frac{\partial F_4(p, P)}{\partial p_k}; \quad \alpha_k = \frac{\partial F_4(p, P)}{\partial P_k}; \quad H' = H + \frac{\partial F_4}{\partial t}$$

So, go here, and again my dF, if I write, if you go back pdq I had here, I can write it as d of pq minus qdp minus this term capital PdQ I can write as d of PQ minus QdP. And then you have your, these terms anyway. So, if I take this total differential and this total differential to the left and combine with F, I get d of F minus pq. So, you have a summation over all these. And then, you have a plus P, capital P, capital PQ, you have some summation here as well. And this is what minus qdp plus capital QdP, this term, and of course, our term with the differential of time.

Now, we will define this as a F4. And F4, I want to see as a function of small p and capital P. So, it is an function of independent variables, small p and capital, capital P. And of course, there is a summation over all indices here. So, as before, I write dF4 as the left del F4 over del p dp plus del F4 over del capital P dP plus del F4 over del t dt and if you compare, you get that minus qk is del F4 pk, that is one, your capital Qk here is this, so delta F4 small p capital P over delta Pk. And your H prime is again H plus partial derivative with respect to time. F4 as a function of p and P.

So, these are our 4 sets of generative functions and the equations that connect the old momenta and the, old coordinates, old canonical coordinates with new canonical coordinates.

And we will give some examples for these in the next video. But I want to end this video with some nomenclature.

(Refer Slide Time: 19:53)

Nomenclature :

- The most general set of transformations over the phase space
 $Q = Q(q, p, t)$
 $P = P(q, p, t)$
are called contact transformations
- A subset of contact trs is canonical trs, they keep the form of Hamilton's canonical eq's unchanged
the trs on the configuration space $Q = Q(q, t)$
are called point transformations.

So, let me write down here. So, the most general set of transformations over the phase space, which is possible are called Contact Transformations. The most general set of transformations over the phase space, which we write as Q . So, you go from small q and capital or small p to capital Q and capital P , so you are able to write them as set functions, where q and p , they all denote a set of q s and set of p s. And these are called canonical transformation, these are called contact transformation. Some colour.

And as I mentioned before or as I said before, if you make such transformations, it is not necessary that equations of motion that you get will appear as, will have the form of the Hamilton's equations. So, a subset of these content transformations will be the ones which will preserve the form of Hamilton's equations of motion and those are called Canonical Transformations.

So, let me write down. A subset of contact transformations is canonical transformations, and they keep the form of Hamilton's canonical equations unchanged, equations unchanged. And the transformations on the configuration space, where only the coordinates are changed, they are called Point Transformations. On the configuration space, where your Q is only a function of q and possibly time, these are called point transformations.

We will, some colour again, canonical transformations and then we have point transformations. So, we will continue further our discussion on Hamiltonian Dynamics in the next video.
