Properties of Lagrangian

Some time back we wrote down Euler Lagrange equations and last time we were looking at some of simple examples where we got to get some practice with using Euler Lagrange equations. Since we have been making Lagrangian as a central thing, let us look at some of its properties now.

(Refer Slide Time 0:49)

Properties of Lagrangian

1. Lagrangian is a scalar
2. A system of N particles
 → two non-interacting parts A, B

$$\vec{r}_A = \{\vec{r}_1, \dots, \vec{r}_m\}, \quad \vec{r}_B = \{\vec{r}_{m+1}, \dots, \vec{r}_N\}$$

$$L = L(\vec{r}_A, \vec{r}_B, \dot{\vec{r}}_A, \dot{\vec{r}}_B)$$

$$= \underbrace{\frac{1}{2} \sum_A m_i \dot{\vec{r}}_i^2}_{L_A} + \underbrace{\frac{1}{2} \sum_B m_j \dot{\vec{r}}_j^2}_{L_B} + U(\vec{r}_A, \vec{r}_B)$$

$$= L_A + L_B + U(\vec{r}_A) + U(\vec{r}_B)$$

So properties of Euler, properties of Lagrangian, first thing is that Lagrangian is a scalar quantity, unlike where you when you use Newton's equations of motion, you have to know forces which are which are vector quantities on all the particles to find out how the system is going to evolve. But when you are using Euler Lagrange equations, what you need to know is the Lagrangian which is made up of the kinetic energy and potential energy. And both of these are scalar quantities. So there is one thing Lagrangian is a scalar. So, for our present context, it is scalar under rotations.

Also, let us say you are looking at a system which has several particles, but you can group the particles into 2 parts. The particles belonging to Part A, let us say one of the parts is called Part A, those particles do not interact with the particles that belong to the part B, so I am imagining a system with 2 parts; Part A and part B, there are also particles in there, the particles within A, they interact among themselves, particles within within B, they interact

among themselves, but the particles from this group do not interact with particles from the other group.

Let us say that is a situation. And can I say something about the Lagrangian of this entire system. And what I want to show is that in such a case the Lagrangian of the entire system can be written as a sum of Lagrangian of individual parts. That is what I want to say and it is quite easy. So, what I am trying to convey is the following. So we have a system of, let us say N particles and I am saying it has two or more than two, it does not matter. You can take more than two also, two or more, let us say two two non-interacting parts, so here is your system, it is isolated from everything else. And let us say it has also particles here and there.

And let us say I can classify these particles into 2 sets. I am not dividing a line; I am not putting a line here to say that this is part A, this is part B because I am imagining the particles are all moving around. But I am saying this guy is belonging to Part A, this guy is going to part B, A, this guy, maybe part B, they do not talk to each other. So, I have two non-interacting parts, A and B by which I mean I mean what I said. So, let me represent by r all the particles or the coordinates of the particles which are belonging to Part A. So, let us say r_1 to r_m belong to that set.

And then r_B denotes all the Cartesian coordinates of the particles which belong to set B. And I write them r_{m+1} to r_n , so that makes a total of, and if you look at both the both the parts, that is good. Now, if I look at the system as a whole, then the Lagrangian of the system, which let me say, let us call it Lagrangian of the system would be a function of r_A , r_B , it depends on all the coordinates of all the particles in in in general, that is a general statement, r_A dot, it also depends on all the velocities of each of the particles that is what our system is.

Now, this you know what form it has, it has the form of kinetic energy minus the potential energy. So, I will write it as $\frac{1}{2} m_i \dot{r}_i^2$ and I have to sum over all the particles, but I will split this sum into two parts, I will submit because I can this is an ordinary sum. So, first you have sum over all the particles belonging to the class to the to the part A, then again you have half and let me put j , it does not matter you can put i as well, but I will just put j , there is no special reason for that.

And here are some over all the particles which belong to set B and then you have the potential energy which depends on all the particles in the system. Let, so in shorthand I write it like this. That is good. Now, if the potential if the parts are not interacting, then the

potential energy of the entire system can be written as the potential energy of the Part A plus the potential energy of the Part B, that is what it means by non-interacting.

So, that is what I will do. Because they are not interacting, this U can be written as U of r A plus U of r B, it can be split into two such parts. Maybe I should use a different symbol for U, but because it is clear from here that these are energies corresponding to part A and Part B so, I will not bother with writing the changing the symbol for you for these individual parts.

If that is the case, then this Lagrangian as you can see, I can combine this piece with this and that piece with this. So, I get L of A that is the Kinetic plus potential energy of that part plus L of B that is one thing which you wanted to show. So, this splitting can be done only if these parts are not interacting with each other. Otherwise, it makes no sense, you cannot we cannot do this. Also, let us go to next page.

(Refer Slide Time 10:43)

3. Lagrangian is not uniquely determined.

$$L, L' : L' = L + \frac{df}{dt}$$

$$F(q, t)$$

Proof: $\frac{d}{dt} \frac{\partial L(q, \dot{q}, t)}{\partial \dot{q}} - \frac{\partial L}{\partial q} = 0$

$\frac{d}{dt} \frac{\partial}{\partial \dot{q}} \left(\frac{df}{dt} \right) - \frac{\partial}{\partial q} \frac{df}{dt} \leftarrow$ extra on L.H.S

$\frac{d}{dt} \frac{df}{dt} = \frac{\partial}{\partial t} \left(\frac{\partial F}{\partial t} + \frac{\partial F}{\partial q} \dot{q} \right) = \frac{\partial F}{\partial t}$ | $\frac{\partial F}{\partial t}$ is not a f of q

$I = \frac{d}{dt} \frac{\partial F}{\partial \dot{q}} = \frac{\partial}{\partial t} \frac{\partial F}{\partial \dot{q}} + \frac{\partial}{\partial q} \left(\frac{\partial F}{\partial \dot{q}} \right) \cdot \dot{q} = \frac{\partial}{\partial t} \left(\frac{\partial F}{\partial \dot{q}} \right) + \frac{\partial}{\partial q} \left(\frac{\partial F}{\partial \dot{q}} \cdot \dot{q} \right) = \frac{\partial}{\partial t} \left(\frac{df}{dt} \right) = II$

$I - II = 0$

So, I have written down 2 properties, property number 3. It is useful to notice that that the Lagrangian which we are writing, it is not unique, so it is not that if you give a system to me, there is a unique Lagrangian that I can write for it, we will come to this the reason for this also in our later video, but for now I will show that you can add a total time derivative to the Lagrangian and it will still satisfy the equations of motion, it will still satisfy Euler Lagrange equations. So, let me write it down.

So, Lagrangian is not uniquely determined, which means that if I give you 2 Lagrangian L and L prime, they will describe the same system meaning you will get the same Euler Lagrange equations from them provided the L and L prime differ by a total time derivative.

So, more precisely if L' is $L + \frac{dF}{dt}$, where F is a function of all the coordinates, generalized coordinates q_1, q_2 and so forth, and also possibly of time, if this is a situation then L' and L they describe the same system. So, how do I check this? Well, what I should do is look at the $\frac{dF}{dt}$ term and plug into their Euler Lagrange equation.

And if the contribution arising from $\frac{dF}{dt}$, this piece goes to 0 then we can conclude that indeed L' and L satisfy the same equations of motion, they they give the same equations of motion. So, that is what I will do. So proof, I will not bother to give proof for general system with several degrees of freedom, I will just give proof for one degree of freedom, so, I have only one q , but you should try to repeat the proof for a system which has more than one q , but the proof will not be very different, it will follow the same lines which I am going to write on here.

So, let us look at this $\frac{d}{dt}$. Let us say I start with L , $\frac{\delta L}{\delta \dot{q}}$ as I said, I am looking at only one coordinate now, I mean only one degree of freedom \dot{q} and t minus $\frac{\delta L}{\delta q} = 0$. I am saying if I replace this L by $L + \frac{dF}{dt}$, the term coming from the f will go to 0 which means if I plug it in plug in this piece also, then in addition to this, what you have on the left hand side, you will also get the following piece.

You will get $\frac{d}{dt} \frac{\delta}{\delta \dot{q}} \frac{dF}{dt}$ that is correct no mistakes, minus $\frac{\delta}{\delta q} \frac{dF}{dt}$. This is what will get extra on the left hand side. And I would like to show that this is 0, how do I do that? So, let me call this term 1 minus term 2. Let us look at term 1 first. So, I look at this total derivative $\frac{dF}{dt}$. The term one I am looking only $\frac{dF}{dt}$ first. So, $\frac{dF}{dt}$ is remember the F is function of only q and t , not \dot{q} .

So, when I take the total time derivative, I get $\frac{\delta F}{\delta t}$, because I have allowed for an explicit time dependence in F . So, there will be this term plus $\frac{\delta F}{\delta q} \dot{q}$ that is correct. Now, if I take the derivative with respect to \dot{q} on this, let me take $\frac{\delta}{\delta \dot{q}}$ here, over $\frac{\delta}{\delta \dot{q}}$ what will that be? Now, look at this piece, this piece is only a function of q and t because taking a time partial time derivative will not generate any velocity terms.

And this piece will be only a function of q and t this piece, $\frac{\delta F}{\delta q}$, and the time the velocities are only in here. So, when this derivative partial derivative with respect to the generalized velocity X on this piece it gives 0. Here I should use a chain rule but this piece

because it does not depend on velocity, this partial derivative is going to act only on this q dot. So, I get $\frac{\delta f}{\delta q}$ and $\frac{\delta q \dot{}}{\delta q \dot{}}$, which is one so I get $\frac{\delta f}{\delta Q}$. And as I said before, maybe I should write down explicitly $\frac{\delta f}{\delta t}$ is not a function of $q \dot{}$, it is not a function generalized velocities that is good.

Now, I should take the total time derivative, I have taken care of up to here now I should look at the total time derivative of this entire piece. So, I take $\frac{d}{dt}$, now I am taking the total time derivative on the left which means I should let me let me repeat it. Now, I take the total time derivative $\frac{d}{dt}$, this piece, this will become a total time derivative acting on $\frac{\delta F}{\delta q}$ $\frac{\delta F}{\delta q}$, this will be your term number 1 what is that?

Again I do the same thing, I write $\frac{\delta f}{\delta q}$, $\frac{d}{dt}$ so I have first $\frac{d}{dt}$ acting on this piece, then I have $\frac{\delta f}{\delta q}$, $\frac{d}{dt}$ $q \dot{}$. Good, it is not a dot product; this is just a dot, perfect. Now what can I do? That is good, that is good. You see here I can interchange q and t , they are independent variables so I can interchange them, which means I can write this as $\frac{\delta f}{\delta t}$, $\frac{d}{dt}$ $q \dot{}$ plus $\frac{\delta f}{\delta q}$, $\frac{d}{dt}$ $q \dot{}$. If you were looking at more than one degrees of freedom, here your i and j will appear and you will have to take care of those things.

Now this is, so you have $\frac{d}{dt}$ $q \dot{}$ here, $\frac{d}{dt}$ $q \dot{}$ here. So I can write this, I wanted to do one more thing. So, you have $\frac{d}{dt}$ $q \dot{}$ and then I can bring in the $q \dot{}$ in the bracket, I can do so because when you take a derivative of, partial derivative of velocity with respect to coordinate that is 0. So I can I can bring this piece in, which means I can write this as $\frac{d}{dt}$ Q , $\frac{dF}{dt}$ and let us see what our second term was.

Second term was $\frac{d}{dt}$ $q \dot{}$ $\frac{\delta f}{\delta q}$, $\frac{d}{dt}$ $q \dot{}$ which is the same here. So, this is your equal to second term, which means first term minus second term equals 0 and that is what we wanted to prove that the extra term will not give any contribution. That is another very important property that you should keep in mind that you can always add a function to the Lagrangian which can be written as a total time derivative of another function, which depends only on the generalized coordinates and time and not the velocities, that is nice. Let us see what else I can say.

Next, I want to look at the kinetic energy term, when we are using generalized coordinates. So, you know typically when you are using Cartesian coordinates, you have just sum over half $m v$ squares. And when you write V squares you are really summing over velocities of

individual particles and there is no cross term. So, you do not have any term which is a product of velocity of this particle and that particle and the kinetic energy. But this situation changes when you go to generalize coordinates and that is what we want to look at in the next video. So, see you there in the next video.
