Lecture - 56
Magnetohydrodynamics [MHD]: Waves in MHD – Alfven waves and magnetosonic waves

(Refer Slide Time: 00:16)

Now onto waves in a magnetized fluid

- For simplicity (and without loss of generality) $\mathbf{B} = B\hat{z}$
- x and y directions are orthogonal, and for concreteness, we take everything to be uniform along y ; i.e., $\partial_y \rightarrow 0$
- As before, $\rho + \delta\rho$, $P + \delta P$, and now, $\mathbf{B} + \delta\mathbf{B}$, and \mathbf{v} is small
- As before, the linearized continuity equation is $\partial\delta\rho/\partial t + \rho\nabla \cdot \mathbf{v} = 0$
- The linearized equation of motion is slightly different:

$$\rho \frac{\partial \mathbf{v}}{\partial t} = -\nabla \delta P + \frac{1}{4\pi} (\nabla \times \delta \mathbf{B}) \times \mathbf{B}$$

(convince yourself, and compare with linearize eq of motion for plain hydro)

...and the linearized induction equation is

$$\frac{\partial \delta \mathbf{B}}{\partial t} = \nabla \times (\mathbf{v} \times \mathbf{B})$$

"extra term"
 ↓
 arises from $\mathbf{J} \times \mathbf{B}$

Subramanian
Plasma Physics

So, we are back to talking about waves in a magnetized fluid. We have already looked at sound waves which are waves in an unmagnetized fluid and now we looked at the slide yesterday last time we met. And as we remarked the continuity equation is exactly the same, no difference at all. This is the continuity equation and this in particular is a linearized continuity equation, it is no different from how it was earlier.

The linearized equation of motion which is the momentum equation that contains this extra part. This is the extra term extra with respect to an unmagnetized situation that is all, right and it arises from the Lorentz force term which is $\mathbf{J} \times \mathbf{B}$ right, but this is not $\mathbf{J} \times \mathbf{B}$ itself.

This is something that needs to be kept in mind. This is a linearized version of $\mathbf{J} \times \mathbf{B}$ and \mathbf{J} is simply curl of \mathbf{B} right. So, so that is the extra term and so, the linearized equation of motion, neglecting viscosity of course, is that and the linearized induction equation is this ok.

(Refer Slide Time: 01:52)

Components..

Splitting the equations of motion and induction into components (simplest thing to do):

$$\rho \frac{\partial v_x}{\partial t} = -\frac{\partial P}{\partial x} + \frac{B}{4\pi} \left(\frac{\partial \delta B_x}{\partial z} - \frac{\partial \delta B_z}{\partial x} \right), \quad \rho \frac{\partial v_z}{\partial t} = -\frac{\partial P}{\partial z},$$

$$\rho \frac{\partial v_y}{\partial t} = \frac{B}{4\pi} \frac{\partial \delta B_y}{\partial z},$$

$$\frac{\partial \delta B_x}{\partial t} = B \frac{\partial v_x}{\partial z}, \quad \frac{\partial \delta B_z}{\partial t} = -B \frac{\partial v_x}{\partial x},$$

$$\frac{\partial \delta B_y}{\partial t} = B \frac{\partial v_y}{\partial z}$$

Somewhat lengthy, but straightforward

Subramanian Plasma Physics

So, now before going on what we did was we said it is simple to split up split up these vector equations in components x, y and z right. Recognizing that the magnetic field is only in the z direction ok. So, the magnetic field is just in the z direction and all we are writing now all we

are doing now is writing down the equations in blue this, this and this in components that is all.

So, it is somewhat lengthy, but straightforward really and the first thing to realize now is that you know these two equations in red right. So, that was the comment that I made last time. It is somewhat lengthy, but straight forward. It is really no big issue to write down these three equations in component form. The remarkable fact right now is we will consider magneto sonic waves in due course.

(Refer Slide Time: 03:05)

Components..

Splitting the equations of motion and induction into components (simplest thing to do):

$$\rho \frac{\partial v_x}{\partial t} = -\frac{\partial \delta P}{\partial x} + \frac{B}{4\pi} \left(\frac{\partial \delta B_x}{\partial z} - \frac{\partial \delta B_z}{\partial x} \right), \quad \rho \frac{\partial v_z}{\partial t} = -\frac{\partial \delta P}{\partial z},$$

$$\frac{\partial \delta B_x}{\partial t} = B \frac{\partial v_x}{\partial z}, \quad \frac{\partial \delta B_z}{\partial t} = -B \frac{\partial v_x}{\partial x}, \quad \frac{\partial \delta B_y}{\partial t} = B \frac{\partial v_y}{\partial z},$$

$$\rho \frac{\partial v_y}{\partial t} = \frac{B}{4\pi} \frac{\partial \delta B_y}{\partial z},$$

Only δB_y & δv_y ↓

Of these, the equations dealing with the y components of the velocity and magnetic field are not coupled to the other components. So one can set $v_x = v_z = \delta B_x = \delta B_z = \delta P = \delta \rho = 0$ and still expect a nontrivial solution for v_y and B_y .

Subramanian Plasma Physics

But at the moment the remarkable thing to recognize is that the y components you know of these two equations this is a this arises from the induction equation and that arises from the continuity equation that y components of the velocity and magnetic field are not coupled to any of the other components.

You see you have v_y here and you have δB_y here; you have you have δB_y here and v_y here. They do not talk to there is no appearance of δB_z or anything or for that matter v_z in these two equations. So, that is what a one means by saying that the y components of the velocity and magnetic fields are not coupled to the other components.

Another way of thinking about this is to say that you can simply set the x and z components of the velocity as well as the magnetic field you know perturbations and for that matter even the pressure perturbation and the density perturbation equal to 0. And still you can expect a nontrivial solution for v_y and B_y ok.

So, this is also pointing to the fact that here we are concerned only with only δv_y and δB_y that is it.

(Refer Slide Time: 04:38)

In other words you have you have a magnetic field pointing in the z direction right \hat{z} and so, so this would be there right and suppose this was the this was the y direction ok. So, we are considering a perturbation of the magnetic field that looks like this right.

So, in other words you only have, so, this is a y direction right. So, so the magnetic field is perturbed in the y direction you see and the velocity also the velocity is also perturbed in the y direction. So, this is the situation that we are considering ok.

(Refer Slide Time: 05:34)

In other words transverse perturbations; we are talking about perturbations of v and B that is what one means by this right. Transverse to what? Well, transverse to the to the uniform magnetic field direction ok. So, that is the main thing I want to I want to emphasise here right and so, we are considering a mode that arises only from transverse perturbations of v and B .

This gives rise to the important to the Alfvén mode. This is a very important mode of wave propagation and let us now go ahead and see what the properties of this of Alfvén mode are right.

(Refer Slide Time: 06:46)

Alternatively..

θ is the \angle w.r.t z .

$$\begin{pmatrix} v_\phi^2 - v_A^2 - c_s^2 \sin^2 \theta & 0 & -c_s^2 \sin \theta \cos \theta \\ 0 & v_\phi^2 - v_A^2 \cos^2 \theta & 0 \\ -c_s^2 \sin \theta \cos \theta & 0 & v_\phi^2 - c_s^2 \cos^2 \theta \end{pmatrix} \begin{pmatrix} v_x \\ v_y \\ v_z \end{pmatrix} = 0$$

Note, the equation for v_y is decoupled from the others.

Equivalent way

Subramanian Plasma Physics

Alternatively, I would say never mind this slide. This is an exact thing as this is written in a slightly different form. I have written in terms of theta which is the angle with respect to the z axis and we have already introduced the Alfvén velocity and the sound speed is exactly the same ok. So, you have this, this matrix multiplying the velocity vector and that is equal to 0.

And so, in order for a nontrivial solution to exist the determinant of this matrix needs to be 0. So, it is an equivalent way of representing it. We will not I just wanted to show it to you, but we will not concern ourselves with this way of representing it anymore.

(Refer Slide Time: 07:31)

Alfvén waves

the two equations for the y components give

$$\left(\frac{\partial^2}{\partial t^2} - v_A^2 \frac{\partial^2}{\partial z^2} \right) (\delta B_y, v_y) = 0$$

$$\frac{\partial^2 \delta B_y}{\partial t^2} - v_A^2 \frac{\partial^2 \delta B_y}{\partial z^2} = 0$$

(Refer Slide Time: 07:32)

Alfvén waves

the two equations for the y components give

$$\left(\frac{\partial^2}{\partial t^2} - v_A^2 \frac{\partial^2}{\partial z^2} \right) (\delta B_y, v_y) = 0, \quad v_A^2 = \frac{B^2}{4\pi\rho} \rightarrow \text{Alfvén speed}$$

Some salient properties of the Alfvén wave:

"Looks like" the sound speed, but there are differences.

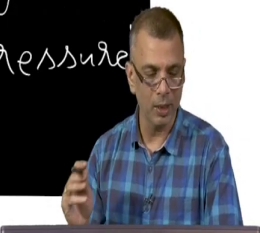

Subramanian Plasma Physics

So, the thing is when you ah look at these two equations right these are two coupled first order equations and you can you know you can parlay them into one coupled second order equation exclusively in delta v y or exclusively in delta P y. And that is what this is.

So, you have an equation which looks like d square dt square of delta B y minus this quantity v A squared times d squared d z square of delta B y equals 0 or the very same equation with delta B y replace by v y that is it ok, where this all important ah thing v A squared this is the Alfvén speed ok. It looks like the sound speed, but there are important differences. And let us see what those differences are right.

(Refer Slide Time: 09:01)

$$C_s^2 \equiv \frac{\delta P}{\delta \rho} \sim \frac{P \rightarrow \text{Gas press.}}{\rho \rightarrow \text{density}}$$
$$V_A^2 \equiv \frac{B^2/4\pi}{\rho} \quad \left. \begin{array}{l} \text{Magnetic} \\ \text{pressure} \end{array} \right\}$$

So, you see the sound speed if you remember was written as you know C_s squared was $dP/d\rho$ which we sort of carelessly can write it as P/ρ ok, where this was a gas pressure and this is the density gas density. Whereas the Alfvén speed which we just define is given by B^2 squared over $4\pi\rho$.

I beg a pardon I wonder if it's B^2 squared over $8\pi\rho$ yeah 4π sorry. So, it's B^2 squared over $4\pi\rho$ divided by ρ . So, I say this and that look very similar. So, the ρ appearing in the denominator is the same and this is the magnetic pressure. In what sense is the magnetic pressure?

If you remember we wrote down the magnetic stress tensor right and this would be the diagonal term in the magnetic stress tensor ok. And you know that in any kind of pressure the diagonal term is interpreted as the scalar pressure ok. So, in that sense this can be interpreted

as a magnetic pressure. So, this and that the expressions for the Alfvén speed and the sound speed look quite identical.

(Refer Slide Time: 10:39)

Except there are differences there are important differences important differences. The sound wave is longitudinal, right. In other words the \mathbf{k} that the propagation vector of the wave is a long pressure and the sound wave essentially let me finish this.

In other words the density and pressure perturbations are along the direction of propagation \mathbf{k} , whereas, here you see and Alfvén wave by definition that is the direction of propagation along. So, this wave you know it travels along the z direction along the direction of the \mathbf{a} unperturbed magnetic field, but the perturbations are transverse. You see the perturbations are in the y direction.

So, the Alfvén wave, the Alfvén wave is transverse. So, this is one very important difference between the sound wave and Alfvén wave. Although the expressions for the sound speed and the Alfvén speed look quite similar with simply with the magnetic pressure replacing the gas pressure ok, but the nature of the waves are quite different. So, this is something that I wanted to sort for emphasise and is vary the Alfvén wave.

(Refer Slide Time: 12:26)

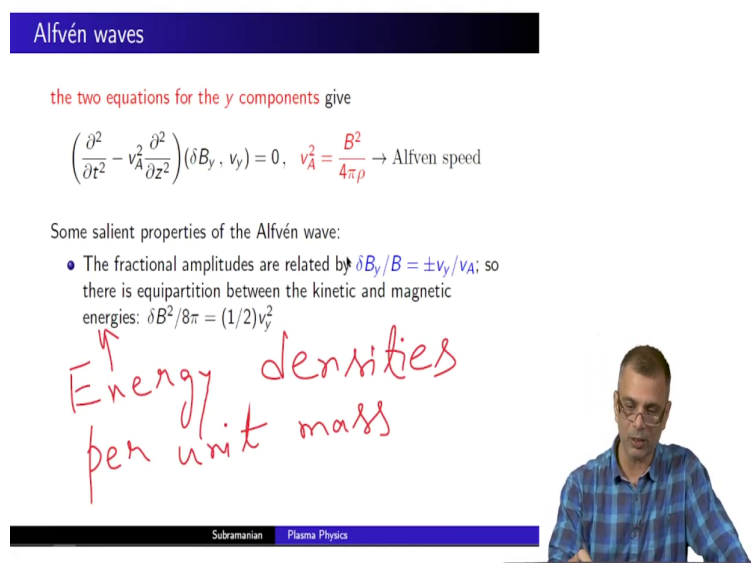

ah Alfvén wave is much like wave on a string right that is exactly what you know. Say you have a string like this and you know I fasten at both ends and so, it has a certain tension a on it and you are toying it, right. You give you know that kind of a perturbation to it and you have you know as a result you have waves propagating like this.

Those would be waves and a string and that looks exactly like the Alfvén wave. You see the magnetic field is like a string in the z direction and is as if the magnetic field which is an

elastic kind of a thing, the magnetic field line which is like a rubber band its being twanged and transverse perturbations on this rubber band or propagating along the magnetic field direction right.

So, in that sense the Alfvén wave is much like a transverse wave I should say transverse wave on a string ok. So, this is something important to keep in mind as we go ahead.

(Refer Slide Time: 13:54)

Alfvén waves

the two equations for the y components give

$$\left(\frac{\partial^2}{\partial t^2} - v_A^2 \frac{\partial^2}{\partial z^2} \right) (\delta B_y, v_y) = 0, \quad v_A^2 = \frac{B^2}{4\pi\rho} \rightarrow \text{Alfvén speed}$$

Some salient properties of the Alfvén wave:

- The fractional amplitudes are related by $\delta B_y / B = \pm v_y / v_A$; so there is equipartition between the kinetic and magnetic energies: $\delta B^2 / 8\pi = (1/2) v_y^2$

Energy densities per unit mass

Subramanian Plasma Physics

The other things some other salient properties so, the Alfvén waves that the fractional amplitudes are similar in otherwise $\delta B / B$ is the same as v_y / v_A . I simply write v_y because this really no need to write that v_y there was no average v to start with.

So, the small v_y is indeed a delta quantity ok and an immediate consequence of this is that there is equipartition between the kinetic and magnetic energies. In other words the energy in

the magnetic field perturbations is $\delta B^2 / 8\pi$ right and energy density. Actually I should say energy density energy densities to be precise. I should not I mean I have been a little it is not so much energies, but it really should be energy densities.

So, the this will bit of a lose way of saying it. So, the $\delta B^2 / 8\pi$ is the energy density in a magnetic field perturbations and half v^2 squared energy densities again per unit gram per unit mass. So, this as you can recognize is the kinetic energy kinetic energy you know per unit mass right.

So, so this would be energy density specific energy densities and there is equipartition ok. The magnetic energy density and the kinetic energy density are the same and this is a simple consequence of this fact ok.

(Refer Slide Time: 15:32)

Alfvén waves

the two equations for the y components give

$$\left(\frac{\partial^2}{\partial t^2} - v_A^2 \frac{\partial^2}{\partial z^2} \right) (\delta B_y, v_y) = 0, \quad v_A^2 = \frac{B^2}{4\pi\rho} \rightarrow \text{Alfvén speed}$$

Some salient properties of the Alfvén wave:

- The fractional amplitudes are related by $\delta B_y / B = \pm v_y / v_A$; so there is equipartition between the kinetic and magnetic energies: $\delta B^2 / 8\pi = (1/2) \rho v_y^2$
- Alfvén waves are dispersionless: $\omega^2 = k_z^2 v_A^2$

$e^{ikx - i\omega t}$
 $k_z, \text{ not } k$

Subramanian
Plasma Physics

Alfven waves are also dispersion less. If you assume $e^{i(kx - \omega t)}$ this kind of a dependence for the δB_y as well as v_y . What happens is this $\frac{d^2}{dt^2}$ becomes minus ω^2 right and sorry ω^2 just becomes ω^2 and the $\frac{d^2}{dz^2}$ becomes you know minus k^2 .

And so, just from this you can figure this out ok. This is the dispersion relation and as with again this is similar to the sound mode. As with the sound wave rather the sound waves are also dispersion less and so, are the Alfven waves. The $\frac{\omega}{k_z}$ or the $\frac{d\omega}{dk_z}$ are both not functions of ω itself. They simply involve the same velocity.

However, please remember this is k_z not k , not k itself. This is k only along the z direction only along the magnetic field direction. So, please this is one important difference between sound wave and the Alfven wave ok.

(Refer Slide Time: 16:58)

So, so the dispersion relation for a sound wave is ω^2 equals $c_s^2 k^2$ square like that. Alfvén wave is ω^2 equal $v_A^2 k_\parallel^2$ square, very important ok. First of all the whole point is that the Alfvén wave is like a transverse wave on a string and the string is the magnetic field.

So, the appearance of a magnetic field breaks a symmetry. Here that the k is the same in all directions you see. There is nothing to distinguish one direction from the other. Here the presence of a magnetic field immediately sets a preferred direction ok. So, it breaks symmetry and so, the k in one direction is not the same as a k in other directions ok.

Specifically, the k along the magnetic field is different from the k perpendicular to the magnetic field and here we are referring to I know k_z , in other words the k along the magnetic field ok. So, this is very important to keep in mind. So, k_z , not k right.

(Refer Slide Time: 18:24)

Alfvén waves

the two equations for the y components give

$$\left(\frac{\partial^2}{\partial t^2} - v_A^2 \frac{\partial^2}{\partial z^2} \right) (\delta B_y, v_y) = 0, \quad v_A^2 = \frac{B^2}{4\pi\rho} \rightarrow \text{Alfvén speed}$$

↕

Some salient properties of the Alfvén wave:

- The fractional amplitudes are related by $\delta B_y/B = \pm v_y/v_A$; so there is equipartition between the kinetic and magnetic energies: $\delta B^2/8\pi = (1/2)\rho v_y^2$
- Alfvén waves are dispersionless: $\omega^2 = k_z^2 v_A^2$ (?)
- It involves only k_z ; in other words, the waves propagate along the magnetic field
- Its transverse: $\delta \mathbf{B}$ and \mathbf{v} are $\perp \mathbf{k}$ as well as \mathbf{B} .

Much like waves on a string

Subramanian
Plasma Physics

It involves only k_z yeah. So, so that is what that is clearly the case. In other words the waves propagate along the magnetic field like we have said and its transverse the δB and v are perpendicular to k as well as to B as we have already remarked they are much like waves on a string ok.

(Refer Slide Time: 18:50)

Alfvén waves

the two equations for the y components give

$$\left(\frac{\partial^2}{\partial t^2} - v_A^2 \frac{\partial^2}{\partial z^2} \right) (\delta B_y, v_y) = 0, \quad v_A^2 = \frac{B^2}{4\pi\rho} \rightarrow \text{Alfvén speed}$$

Some salient properties of the Alfvén wave:

- The fractional amplitudes are related by $\delta B_y/B = \pm v_y/v_A$; so there is equipartition between the kinetic and magnetic energies: $\delta B^2/8\pi = (1/2)\rho v_y^2$
- Alfvén waves are dispersionless: $\omega^2 = k_z^2 v_A^2$ (?)
- It involves only k_z ; in other words, the waves propagate along the magnetic field
- Its transverse: $\delta \mathbf{B}$ and \mathbf{v} are $\perp \mathbf{k}$ as well as \mathbf{B}
- There is no $\delta\rho$, so Alfvén waves are incompressible

Subramanian Plasma Physics

The other thing is that the other important differences that there is no appearance of delta rho. There are if you remember we could hear you see we had said we could get nontrivial solutions to these two equations with delta rho actually being equal to 0. No density perturbations that is one way of looking at it the other way of looking at it is that nowhere in this equation thus delta rho make an appearance right.

So, therefore, Alfvén waves do not involve density perturbation and all. therefore, Alfvén waves are incompressible; very very important point and this is a important point of distinction with the sound waves. Sound waves are compressible that is a whole point of sound waves ok. Sound waves involve compressions in density as well as delta rho and delta P.

Here neither $\Delta \rho$ nor ΔP makes an appearance. So, Alfvén waves are incompressible. So, although the expressions for the Alfvén speed and the sound speed look similar there are several points of difference between the sound speed and the Alfvén speed and these are important to note right.

(Refer Slide Time: 20:10)

Hannes Alfvén (1908 - 1995)

Nobel Prize in Physics (1970)
http://www.nobelprize.org/nobel_prizes/physics/laureates/1970/alfven-lecture.pdf
Cosmical Electrodynamics

Subramanian Plasma Physics

So, let us go ahead. This is a picture of Hannes Alfvén. He won the Nobel Prize in Physics in 1970 for many things, but you know and I urge you to look up this website very interesting website which contains his Nobel Prize lectures, where the lecture he delivered while accepting the Nobel Prize and is called Cosmical Electrodynamics. It is very instructive. I would strongly urge you to go through it at least glance through it once right ok.

(Refer Slide Time: 20:49)

The non-Alfvén wave solutions - I

• These wave solutions are consequences of compressibility, i.e., $\delta\rho$ is central

unlike the Alfvén wave.

Subramanian Plasma Physics

So, now let us now move to the non Alfvén wave solutions the remember we split up the three equations in components and we marked only the ones which involve only the y components we mark them in red. Now, how about the other solutions right? So, we marked the once which involve only the y components we mark them in red and we found that they represent Alfvén waves.

They represent a particular kind of wave which is transverse which in other words the perturbations or transverse of velocity and the magnetic field perturbations or transverse like this right and involved involves the they are transverse and involve no δP and $\delta\rho$. So, they are incompressible right and so, these are the this is just to you know a these are Alfvén Alfvénic perturbations ok.

Now, turns out the other solutions are consequences of compressibility. In other words unlike the Alfvén solution the appearance of δP is very important unlike the Alfvén wave. The Alfvén wave is incompressible there is no need to invoke a $\delta \rho$ and a δP . Here the $\delta \rho$ is central as we for these particular kinds of waves.

(Refer Slide Time: 22:36)

The non-Alfvén wave solutions - I

- These wave solutions are consequences of *compressibility*, i.e., $\delta \rho$ is central
- It's easier to proceed using Fourier components;

$\frac{\partial}{\partial t} \rightarrow i\omega \rightarrow \text{one temporal freq.}$
 $\frac{\partial}{\partial x} \rightarrow ik \rightarrow \text{one spatial freq.}$

Subramanian Plasma Physics

It is easier to proceed using Fourier components. In other words wherever you see d over dt you write it as $i\omega$, wherever you see d over dx you write it as ik . And there can be a minus $i\omega$ or there can be a minus ik depending upon exactly how you write $e^{i\omega t - kx}$ or $e^{i\omega t + kx}$. So, it does not matter.

So, this is essentially what I mean by this. So, instead of the differential equations you will get algebraic equations and the only slight disadvantage there is that you will be

dealing only with one temporal frequency and one spatial frequency or spatial wave number ok.

Only with one value of omega and one value of k at a time when you are doing Fourier components, but that is ok the equation is linear. So, the behavior for other frequencies; spatial and temporal can be then superposed linearly superpose. So, you have the solution for one, the solution for the others look exactly the same, the functional dependencies are exactly the same; that is the whole advantage of doing Fourier language right.

(Refer Slide Time: 24:17)

The non-Alfvén wave solutions - I

- These wave solutions are consequences of *compressibility*; i.e., $\delta\rho$ is central
- Its easier to proceed using Fourier components; i.e., assume that all quantities vary as $\exp i(\omega t - \mathbf{k} \cdot \mathbf{x})$
- So time derivatives are $i\omega$ and space derivatives are $-ik$
- In this language, the linearized mass continuity equation $\partial\delta\rho/\partial t + \rho\nabla \cdot \mathbf{v} = 0$ becomes
- $\delta\rho - \rho\mathbf{k} \cdot \mathbf{v}/\omega = 0 \rightarrow$ *lin cont eq. in Fourier*
- Using the definition of the adiabatic sound speed $\delta P \equiv c_s^2 \delta\rho$, this gives $\delta P = c_s^2 \rho \mathbf{k} \cdot \mathbf{v}/\omega$

Subramanian

Plasma Physics

So, I i assume that it is an exponential i omega t minus k dot x right. So, therefore, all time derivatives of i omega and all space derivatives are minus i k right. So, in this language the linearized mass continuity equation which is this becomes that right. So, it is quite simple.

The $\frac{d}{dt}$ became an $i\omega$ and the divergence of \mathbf{v} became $i\mathbf{k} \cdot \mathbf{v}$ that is its. So, that is how you get this the this is the same thing as the mass continuity equation. So, this is really the mass continuity linearized continuity equation in Fourier language that is what this is.

Instead of ρ we can we can you know rather instead of $\delta\rho$ if we prefer to write things in terms of δP then you have to invoke the sound speed. So, so, this is the same as this except you have we have now invoke the sound speed to eliminate the $\delta\rho$ in favour of δP . So, this again is the same equation linearized continuity equation in Fourier language ok.

(Refer Slide Time: 25:40).

To recap..

we're looking at:

Alfvén wave solⁿ

$$\rho \frac{\partial v_x}{\partial t} = -\frac{\partial \delta P}{\partial x} + \frac{B}{4\pi} \left(\frac{\partial \delta B_z}{\partial z} - \frac{\partial \delta B_x}{\partial x} \right), \quad \rho \frac{\partial v_z}{\partial t} = -\frac{\partial \delta P}{\partial z},$$

$$\rho \frac{\partial v_y}{\partial t} = \frac{B}{4\pi} \frac{\partial \delta B_y}{\partial z},$$

$$\frac{\partial \delta B_x}{\partial t} = B \frac{\partial v_x}{\partial z}, \quad \frac{\partial \delta B_z}{\partial t} = -B \frac{\partial v_x}{\partial x},$$

$$\frac{\partial \delta B_y}{\partial t} = B \frac{\partial v_y}{\partial z}$$

Same system of Eqs

Subramanian Plasma Physics

So, just to recap we are looking at the same system of equations, except we had originally looked at this and this. These gave the Alfvén wave solution right. This equation this equation

they together they gave the Alfvén wave solution. Now, what we are going to do is we are going to look at the remaining equations which is this, this, this and this ok.

And what is more? We are not going to bother about; just for convenience rather, we will not look at the differential equations themselves. We will look at the Fourier analyzed versions of the differential equations where the d/dt becomes an $i\omega$ and the d/dx becomes an ik ok.

So, and other important thing to remember is that you have the appearance of δP s here. You see δP s or $\delta \rho$ s for that manner you have a δP here you have δP here. So, therefore, clearly these modes do involve pressure and density perturbations and these are central to the understanding of these modes and therefore, these kinds of modes are necessarily compressible ok.

And these modes are called magneto sonic mode. Sonic because they are like sound waves in that they involve compressibility and magneto sonic in that there sound waves modified by the presence of a magnetic field. And so, these magneto sonic waves are split into two varieties. One is a fast magneto sonic wave and one is a slow magneto sonic wave and we will discover soon enough that they have very interesting properties in some particular situations depending upon the angle of propagation of the wave with respect to the large scale magnetic field.

The magnetic field again is always along the z direction ok that can always be assumed without loss of generality depending upon the direction of propagation of these magneto sonic waves with respect to the magnetic field of course. Sometimes they start looking like the sound waves sometimes they do not. Sometimes they look very much like the Alfvén wave. So, we will analyze these solutions when we meet next. So, for the time being there is it.

Thank you.
