Lecture - 37
MicroCanonical to Canonical – Part II

(Refer Slide Time: 00:15)

$$\begin{aligned}
 \rho_1(p_1, q_1) &= \frac{1}{V} \left[\frac{2\pi m}{\beta} \right]^{1/2} e^{-\frac{\beta p_1^2}{2m}} \quad \beta = \frac{1}{k_B T} \\
 &= \frac{1}{V} \frac{1}{\sqrt{2\pi m k_B T}} e^{-\frac{\beta p_1^2}{2m}} \\
 \rho_1(p_1, q_1) &= \frac{1}{V} \sqrt{\frac{\beta}{2m\pi}} e^{-\beta p_1^2/2m} \\
 \rho_1(p_1, q_1) &= \left(\frac{1}{V} \sqrt{\frac{\beta}{2m\pi}} e^{-\beta p_1^2/2m} \right) \\
 \rho_1(p) &= \int \rho_1(p, q) dq = \rho_1(p, q) \int dq = \left(\frac{1}{V} \sqrt{\frac{\beta}{2m\pi}} e^{-\beta p^2/2m} \right) \int dq \\
 &= \sqrt{\frac{\beta}{2m\pi}} e^{-\beta p^2/2m}
 \end{aligned}$$

Welcome back. So, we saw how the ideal gas result I mean one can go from the Micro Canonical to the Canonical.

(Refer Slide Time: 00:28)

Set of Classical Harmonic Oscillators.

$$\rightarrow \mathcal{H} = \sum_i \frac{p_i^2}{2m} + \frac{1}{2} \sum_i m\omega^2 q_i^2 \quad \text{One dimensional}$$

$$q_i = \frac{q_i'}{m\omega} \quad \mathcal{H} = \sum_i \frac{p_i^2}{2m} + \frac{1}{2} \sum_i m\omega^2 \frac{q_i'^2}{(m\omega)^2} = \sum_i \frac{p_i^2}{2m} + \frac{1}{2} \sum_i \frac{q_i'^2}{m}$$

$2mE = \sum_i \left(\frac{p_i^2}{m} + q_i'^2 \right) \rightarrow$ Hypersphere \rightarrow in a $2N$ Dimensional phase space

$$\Omega = \frac{1}{h^N} \int_{\mathcal{HSE}} dp_1 \dots dp_N dq_1 \dots dq_N = \frac{1}{h^N} \frac{1}{(m\omega)^N} \int_{\mathcal{HSE}} dp_1 \dots dp_N dq_1' \dots dq_N'$$

\equiv Volume of the Hypersphere
 \downarrow
 $2N$ Dimensional
 phase space

Now, we want to take another example and that is of a set of classical Harmonic Oscillators. The Hamiltonian of the system was π square over twice m plus half sum over m omega square q_i square. This is a one dimensional case; the generalization to higher dimensions is very trivial to do.

So, that when we did this in the micro canonical ensemble, we essentially made a change of variable where we had written that q is q' divided by m omega so, that the Hamiltonian is π square over twice m plus half of sum over i m omega square q_i' square over m omega whole square, and that gives me sum over i π square over twice m plus half sum over q_i' square over twice m .

So, the hyper surface so essentially, the hyper surface is given by twice mE is sum over i π square plus q_i square and you are looking at a hyper sphere just as we had for an ideal gas

except that this is in a 6th sorry this is N dimensional so, you are looking at a 2N dimensional phase space. So, please be careful in keeping count of the dimension of the phase space because, I have started with one dimensional I come up with 2 N dimensional.

N coordinate and N sorry N momenta and N coordinate. The total number of microstates we calculated was h to the power N integral h of E less than equal to E dp 1 to dp N dq 1 to dq, N which in using the transform variable becomes 1 over m omega raised to the power N h less than equal to E dp 1 to dp N and then I have dq 1 prime to dq N prime, and this is equivalent to the volume of the hyper sphere in 2 N dimensional phase space.

(Refer Slide Time: 03:46)

$$\begin{aligned}
 \Omega &= \frac{1}{h^N} \int_{XSE} dp_1 \dots dp_N dq_1 \dots dq_N = \frac{1}{h^N} \frac{1}{(m\omega)^N} \int_{XSE} dp_1 \dots dp_N dq_1' \dots dq_N' \\
 &\equiv \text{Volume of the Hypersphere} \\
 &\quad \text{in } 2N \text{ dimensional phase space} \\
 \Omega(E, N) &= \frac{1}{h^N} \frac{1}{(m\omega)^N} \frac{2\pi^N}{\Gamma(N+1)} (2mE)^N \\
 &\downarrow \text{Joint probability Density} \\
 \rho_N(p_1, q_1, p_2, q_2, \dots, p_N, q_N) &= \frac{1}{\Omega} \\
 &\downarrow \\
 \rho_1(p_1, q_1) &\rightarrow \text{Integrating over } (p_2, q_2), (p_3, q_3) \dots (p_N, q_N)
 \end{aligned}$$

Now, I know what this volume is please note that there is no N factorial here, because these particles are distinguishable by their position. The mean position 1 over m omega raised to the power N 2 pi to the power N divided by gamma N plus 1, remember that the general

result for a volume of a hyper sphere in D dimension was $2 \pi^{D/2}$ divided by $\Gamma(D/2 + 1)$ raised to the power R to the power D by 2; and in this case D is equal to 2N I have twice m E raised to the power N.

So, starting from this expression, I can define the N probe N particle joint probability density ρ_N of $p_1, q_1, p_2, q_2, \dots, p_N, q_N$ as $1/\Omega$. So, this is the joint probability density and our interest lies in the single particle probability density ρ_1 of p_1, q_1 for one particle to be in a microstate defined by p_1, q_1 and this we do by integrating over $p_2, q_2, p_3, q_3, \dots, p_N, q_N$, the other degrees of freedom.

(Refer Slide Time: 05:33)

$$\int_N(p_1, q_1, p_2, q_2, \dots, p_N, q_N) = \Omega$$

$$\downarrow$$

$$\rho_1(p_1, q_1) \rightarrow \text{Integrating over } (p_2, q_2), (p_3, q_3) \dots (p_N, q_N)$$

$$\rho_1(p_1, q_1) = \frac{1}{h} \frac{\Omega(E_{N-1}, N-1)}{\Omega(E, N)}$$

$$\Omega(E_{N-1}, N-1) = \frac{1}{h^{N-1}} \frac{1}{(m\omega)^{N-1}} \frac{2\pi^{N-1}}{\Gamma(N)} (2^m E_{N-1})^{N-1}$$

$$\frac{\Omega(E_{N-1}, N-1)}{\Omega(E, N)} = \frac{1}{h^{N-1}} \frac{1}{(m\omega)^{N-1}} \frac{2\pi^{N-1}}{\Gamma(N)} (2^m E_{N-1})^{N-1} \frac{1}{\left[\frac{1}{h^N} \frac{1}{(m\omega)^N} \frac{2\pi^N}{\Gamma(N+1)} (2^m E)^N \right]}$$

The answer we already know, we have done it in the last lecture and I have ρ_1 in terms of the number of microstates, the single particle partition probability density is given by $1/h \Omega(E, N-1)$ divided by $\Omega(E, N)$.

So, using this expression for the total number of microstates for N particles with energy E I can write down $\Omega(E, N)$. $\Omega(E, N)$ is going to be $\frac{1}{h^{N-1}}$, $\frac{1}{m^{N-1}}$ raised to the power $N-1$ twice by raised to the power $N-1$ divided by $\Gamma(N)$ and I have twice $m E$ not.

So, it has to be E^{N-1} times raised to the power $N-1$. So, the two ratios then becomes $\frac{1}{h^{N-1}}$ $\frac{1}{m^{N-1}}$ divided by $\Omega(E, N)$ is $\frac{1}{h^{N-1}}$ $\frac{1}{m^{N-1}}$ raised to the power $N-1$ 2π to the power $N-1$ divided by $\Gamma(N)$.

And I have twice $m E^{N-1}$ raised to the power $N-1$ $\frac{1}{m^{N-1}}$ over now, we write down the expression for $\Omega(E, N)$ and that is going to be $\frac{1}{h^{N-1}}$ $\frac{1}{m^{N-1}}$ raised to the power 2π to the power N $\Gamma(N+1)$ and I have twice $m E$ raised to the power N .

(Refer Slide Time: 07:37)

$$\begin{aligned}
 \frac{\Gamma(N+1) \pi^{N/2}}{\Gamma(N) \pi^{(N-1)/2}} &= \frac{V^N (m\omega)^N}{V^{N-1} (m\omega)^{N-1}} \frac{\Gamma(N+1)}{\Gamma(N)} \frac{q^{N'}}{2\pi^N} \frac{(2mE_{N-1})}{(2mE)^N} \\
 &= \frac{h}{m\omega} \frac{N}{\pi} \frac{(2mE_{N-1})^{N-1}}{(2mE)^N} \\
 E &= \sum_i \frac{p_i^2}{2m} + \frac{1}{2} \sum m\omega^2 q_i^2 = \frac{p_1^2}{2m} + \frac{1}{2} m\omega^2 q_1^2 + \underbrace{\sum_{i=2}^N \left(\frac{p_i^2}{2m} + \frac{1}{2} m\omega^2 q_i^2 \right)}_{E_{N-1}} \\
 E_{N-1} &= E - \frac{p_1^2}{2m} - \frac{1}{2} m\omega^2 q_1^2 \\
 \frac{\Omega(E_{N-1}, N-1)}{\Omega(E, N)} &= \frac{h}{m\omega} \frac{N}{\pi} \frac{(2m \left[E - \frac{p_1^2}{2m} - \frac{1}{2} m\omega^2 q_1^2 \right])^{N-1}}{(2mE)^N}
 \end{aligned}$$

Let us collect the terms p factors and then we will write down EN minus 1 is so, this is going to be h to the power N h to the power N minus 1 m omega raised to the power N m omega raised to the power N minus 1 gamma of N plus 1 gamma of N. Then, I have 2 pi raised to the power N minus 1 divided by 2 pi raised to the power N I have twice m E N minus 1 raised to the power N minus 1 divided by twice m E raised to the power N.

A lot of cancellations follow and I have h then this gives me over m omega this cancels this N cancels, I have 2, 2 canceling out pi to the power N cancels with pi to the power N, I will be left out with 1 over pi gamma of N plus 1 gamma of N plus 1 is N factorial gamma of N is N minus 1 factorial. So, that I have N coming in the denominator and then I have twice m E N minus 1 raised to the power N minus 1 twice m E raised to the power N.

Now, if you look at the conservation of energy, then the total energy E is going to be sum over i $\frac{p_i^2}{2m} + \frac{1}{2} m \omega^2 q_i^2$. And this I can split as the energy of the first particle which is $\frac{p_1^2}{2m} + \frac{1}{2} m \omega^2 q_1^2$ plus sum over i is equal to 2 to N $\frac{p_i^2}{2m} + \frac{1}{2} m \omega^2 q_i^2$ and this is the part which I identify as the energy of my $N - 1$ oscillators.

So, that this becomes E of $N - 1$. As we had done in the free particle case, so, E of $N - 1$ is then $E - \frac{p_1^2}{2m} - \frac{1}{2} m \omega^2 q_1^2$. Therefore, the ratio $\frac{E_{N-1}}{E} = \frac{E - \frac{p_1^2}{2m} - \frac{1}{2} m \omega^2 q_1^2}{E}$ is going to be $1 - \frac{\frac{p_1^2}{2m} + \frac{1}{2} m \omega^2 q_1^2}{E}$. I am going to have $\frac{p_1^2}{2m} + \frac{1}{2} m \omega^2 q_1^2$ divided by E raised to the power N and this one raised to the power $N - 1$.

(Refer Slide Time: 11:05)

$$\begin{aligned}
 E &= \sum_{i=1}^N \frac{\hbar^2 k_i^2}{2m} + \frac{1}{2} \sum_{i=1}^N m \omega^2 q_i^2 = \frac{\hbar^2}{2m} + \frac{1}{2} m \omega^2 q_1^2 + \underbrace{\sum_{i=2}^N \left(\frac{\hbar^2}{2m} + \frac{1}{2} m \omega^2 q_i^2 \right)}_{E_{N-1}} \\
 E_{N-1} &= E - \frac{\hbar^2}{2m} - \frac{1}{2} m \omega^2 q_1^2 \\
 \frac{\Omega(E_{N-1}, N-1)}{\Omega(E, N)} &= \frac{\hbar}{(m\omega)^{N-1} \pi} \frac{\left(2m \left[E - \frac{\hbar^2}{2m} - \frac{1}{2} m \omega^2 q_1^2 \right] \right)^{N-1}}{(2mE)^N} \\
 &= \frac{\hbar}{\pi} \frac{m\omega}{2mE} \frac{N}{2mE} \\
 &= \frac{\hbar\omega}{2}
 \end{aligned}$$

Once again let us rewrite this by taking one factor of $2mE$ outside this bracket in the denominator so, this gives me \hbar over $m\omega$ is this correct?

(Refer Slide Time: 11:20)

$$\begin{aligned}
 &= \frac{h}{(m\omega)^2} \frac{N}{\pi} \frac{(2mE_{N-1})^{N-1}}{(2mE)^N} \\
 E &= \sum_{i=1}^N \frac{p_i^2}{2m} + \frac{1}{2} \sum_{i=1}^N m\omega^2 q_i^2 = \frac{p_1^2}{2m} + \frac{1}{2} m\omega^2 q_1^2 + \underbrace{\sum_{i=2}^N \left(\frac{p_i^2}{2m} + \frac{1}{2} m\omega^2 q_i^2 \right)}_{E_{N-1}} \\
 E_{N-1} &= E - \frac{p_1^2}{2m} - \frac{1}{2} m\omega^2 q_1^2 \\
 \frac{\Omega(E_{N-1}, N-1)}{\Omega(E, N)} &= \frac{h}{(m\omega)^2} \frac{N}{\pi} \frac{(2m[E - \frac{p_1^2}{2m} - \frac{1}{2} m\omega^2 q_1^2])^{N-1}}{(2mE)^N} \\
 &= \frac{h}{m\omega}
 \end{aligned}$$

Let us just see yeah. So, this is not right because, this is going to be $m\omega$ inverse so, this is $m\omega$ inverse this is a mistake that I made and I have $m\omega$ inverse, which essentially means that I have h by $\pi m\omega$ times N divided by twice mE . And I have if I take the twice m inside the bracket, then essentially I have twice mE minus p_1 square minus m square ω square q_1 square divided by twice mE raised to the power N minus 1. A little simplification then gives me m cancels out h bar ω over.

(Refer Slide Time: 12:20)

$$\begin{aligned}
 \frac{\Omega(E_{N-1}, N-1)}{\Omega(E, N)} &= \frac{h}{(m\omega)^2} \frac{N}{\pi} \frac{\left(\frac{2m}{\hbar^2} \left[E - \frac{\hbar^2}{2m} - \frac{1}{2} m \omega^2 q_1^2 \right] \right)^{N-1}}{(2mE)^N} \\
 &= \frac{h}{\pi} \frac{m\omega}{2mE} \frac{N}{\left[\frac{2mE - \hbar^2 - m\omega^2 q_1^2}{2mE} \right]^{N-1}} \quad N-1 \approx N \\
 &= \frac{h}{\pi} \left(\frac{N}{E} \right) \frac{\left[1 - \frac{\hbar^2 + m\omega^2 q_1^2}{2mE} \right]^{N-1}}{\left[e^{-\frac{(\hbar^2 + m\omega^2 q_1^2)}{2mE}} \right]^{N-1}} \quad E \sim N \\
 &\approx \frac{h}{\pi} \left(\frac{N}{E} \right) e^{-\frac{N}{E} \left(\frac{\hbar^2 + m\omega^2 q_1^2}{2m} \right)} \quad E = Nk_B T
 \end{aligned}$$

So, I have the 2 pi takes care of h bar omega I have h bar omega N over E and this one I can simplify 1 minus p 1 square plus m omega square q 1 square divided by twice m E raised to the power N here, I have again use the approximation N minus 1 is going to be N..

Now, once again you see the argument is that E is an extensive quantity, therefore the E energy scales with N and I can approximate this bracketed expression as e to the power minus p 1 square plus m omega square m square omega square I miss the m square in the above expression q 1 square divided by twice m E.

And this is being raised to the power N. So, that this is h bar omega N by E I have e to the power minus N by E times p 1 square m square omega square q 1 square divided by twice m. Now, for a set of N oscillators I know that E is equal to N K B T in one dimension.

(Refer Slide Time: 13:54)

$$\rho(p_1, q_1) = \frac{1}{h} \frac{\Omega(E_{N-1}, N-1)}{\Omega(E, N)} = \frac{\omega}{2\pi k_B T} e^{-\frac{1}{k_B T} \left(\frac{p_1^2}{2m} + \frac{1}{2} m \omega^2 q_1^2 \right)}$$

Canonical Distribution of a single oscillator.

$$\rho(p, q) = \frac{\omega}{2\pi k_B T} e^{-\frac{1}{k_B T} \left(\frac{p^2}{2m} + \frac{1}{2} m \omega^2 q^2 \right)}$$

$$h_i = \frac{p^2}{2m} + \frac{1}{2} m \omega^2 q^2$$

$$q = \int dp dq e^{-\frac{p^2}{2m}} e^{-\frac{1}{2} m \omega^2 q^2}$$

$$= \int dp e^{-\frac{p^2}{2m}} \int dq e^{-\frac{1}{2} m \omega^2 q^2}$$

So, if I now substitute this result, I have $\bar{\omega} N$ by E is 1 by $K_B T$, $K_B T$ and then I have e to the power minus 1 over $K_B T$ p_1 square over twice m plus half m ω square q_1 square. So, that if you recall ρ of p_1, q_1 was 1 over h ω of E, N minus 1 m minus divided by ω of E, N the ratio of these two quantities. And this becomes, ω over $2\pi K_B T$ e to the power minus 1 over $K_B T$ p_1 square over twice m plus half m ω square q_1 square.

So, this is exactly the canonical distribution of a single oscillator, we have done this in the class and we are also invited to check this. So, essentially since I can choose any arbitrary oscillator I mean I can choose the second oscillator third oscillator. So, p_1, q_1 does not make any sense I can replace this by writing ρ of p, q .

The single particle density as ω over twice by $k_B T$ e to the power minus 1 over $k_B T$ p^2 over twice m plus half a sorry not no longer identified by the index plus half $m \omega^2 q^2$. You can check the normalization of this so, a very briefly if for a single particle the Hamiltonian is given by p^2 over twice m plus half $m \omega^2 q^2$.

And the canonical partition function is Z single particle partition function is q is going to be $\int dp dq e$ to the power minus p^2 over $2m$ e to the power minus β , $\beta m \omega^2 q^2$ by 2. Both these integrals separate out and you have $\int dp \beta p^2$ over twice m dq minus $\beta m \omega^2 q^2$ over 2.

(Refer Slide Time: 16:55)

Handwritten notes showing the derivation of the canonical distribution for a single oscillator:

$$Z_1(p, q) = \frac{1}{h} \frac{\Omega(E_{N-1}, N-1)}{\Omega(E, N)} = \frac{\omega}{2\pi k_B T} e^{-\frac{1}{k_B T} \left(\frac{p^2}{2m} + \frac{1}{2} m \omega^2 q^2 \right)}$$

Canonical Distribution of a single oscillator.

$$Z_1(p, q) = \frac{\omega}{2\pi k_B T} e^{-\frac{1}{k_B T} \left(\frac{p^2}{2m} + \frac{1}{2} m \omega^2 q^2 \right)}$$

$$h_i = \frac{p^2}{2m} + \frac{1}{2} m \omega^2 q^2$$

$$q = \int_{-\infty}^{\infty} dp dq e^{-\beta \left(\frac{p^2}{2m} + \frac{1}{2} m \omega^2 q^2 \right)}$$

$$= \int_{-\infty}^{\infty} dp e^{-\beta \frac{p^2}{2m}} \int_{-\infty}^{\infty} dq e^{-\beta \frac{1}{2} m \omega^2 q^2}$$

$$= \sqrt{\frac{\pi \cdot 2m}{\beta}} \sqrt{\frac{2\pi}{\beta m \omega^2}}$$

Their Gaussian integrals ranges running from minus infinity to plus infinity minus infinity to plus infinity. The first answer is square root of $i 2 m$ over β and the second answer is π

beta m omega square times 2. So, that if you take everything common simplify this 2 m pi by beta into 2 pi over beta m omega square, mass, mass cancels out and this is raised to the power half.

We are going to have 2 pi over beta square omega square 2 pi whole square and this is being raised to the power half; and the single particle partition function becomes twice pi over beta omega. So, this is exactly the factor that you have, beta omega over twice pi which is also the inverse of the normalization.

So now, in both the cases that we have looked at so far essentially our microstates were continuous lessons they are now discrete in microstates; and we would now want to take a look at the system where my microstates are decreased where my microstates are discrete.

(Refer Slide Time: 18:22)

Set of Quantum Oscillators $\{n_i\}$

$$\epsilon_n = (n + \frac{1}{2}) h\omega$$

$$E = \sum_i (n_i + \frac{1}{2}) h\omega = h\omega \sum_i n_i$$

And that essentially corresponds to a set of quantum oscillators. And here you have the energy Eigen values, which are n plus half discrete n plus half $\hbar \omega$ and when we did look at this system using the macro canonical approach we said that the microstates are defined by the occupation numbers n_i right. So, the total energy was given by sum over i n_i plus half $\hbar \omega$, which is sum over i $\hbar \omega$ times n_i .

(Refer Slide Time: 19:11)

$$\epsilon_n = (n + \frac{1}{2}) \hbar \omega$$

$$N \text{ particles with a total energy } E.$$

$$E = \sum_i (n_i + \frac{1}{2}) \hbar \omega$$

$$\frac{E}{\hbar \omega} = \sum_i n_i + \sum_i \frac{1}{2} \Rightarrow \sum n_i = \frac{E}{\hbar \omega} - \frac{N}{2} \quad \frac{M, N}{M, N}$$

$$M = \frac{E}{\hbar \omega} - \frac{N}{2}$$

$$\Omega(M, N) = \frac{(M + N - 1)!}{M! (N - 1)!} \quad \rho_N(n_1, n_2, \dots) = \frac{1}{\Omega}$$

$$\rho_1(n_1) \leftarrow \sum_{n_2, n_3, \dots} \rho_N(n_1, n_2, \dots)$$

So, we can recast this by writing E over $\hbar \omega$ was sum over n_i plus sum over i half and this implied that sum over n_i was E over $\hbar \omega$ minus N by 2. And this sum we call it as M and this is what we had the expression. So, N particles there were N quantum oscillators with a energy with the total energy E .

And this means, that you have the set of numbers integers M and N that we are looking at and we said look this essentially translates to n minus to m balls or m particles and n boxes. How

many possible ways of putting that so, n boxes means $n - 1$ partitions. Therefore, the total number of objects possible was $m + n - 1$ because the two of them are fixed at the ends. So, the total microstates that we obtained was $M + N - 1$ these are all possible permutations that have been considered combinations.

And therefore, the double counting comes if you replay if you change interchange the particles nothing changes and if you interchange the partitions nothing changes we had M factorial $N - 1$ factorial. Now, the idea is I want to determine the single particle density. So, we had $\rho_{n_1 n_2}$ was $1/\Omega$, now from this I want to find out ρ_{n_1} .

And it is the same procedure where we have to sum in order to get this single particle so; we will call it ρ_1 as before and ρ_1 as this. In order to get this quantity I have to sum over n_2 n_3 $\rho_{n_1 n_2}$ right. You will come up with the same expression that we have that we had before except these are discrete microstates so, we do not need the h factor.

(Refer Slide Time: 21:39)

$$M = \frac{E}{\hbar\omega} - \frac{N}{2}$$

$$\Omega(M, N) = \frac{(M+N-1)!}{M!(N-1)!} \quad \rho_N(n_1, n_2, \dots) = \frac{1}{\Omega}$$

$$\rho_1(n_1) \leftarrow \sum_{n_2, n_3, \dots} \rho_N(n_1, n_2, \dots)$$

$$\rho_1(n_1) = \frac{\Omega(E_{N-1}, N-1)}{\Omega(E, N)} \quad E = \left(n_1 + \frac{1}{2}\right)\hbar\omega + \sum_{i=2}^N \left(n_i + \frac{1}{2}\right)\hbar\omega$$

$$\frac{E}{\hbar\omega} = \left(n_1 + \frac{1}{2}\right)$$

So, essentially rho 1 of n 1 was going to be omega of E minus so, we will write down E N minus 1 with N minus 1 particle divided by E comma N. The h factor is not there right because, here that microstates are discrete so, there any case dimensionless number. Now, if I have n minus 1 particles that means, E is going to be N 1 plus half h bar omega minus sum over i n i plus half sorry plus n i plus half h bar omega. So, that E over h bar omega is going to be n 1 plus half and this sum runs from i equal to 2 to N.

(Refer Slide Time: 22:50)

4

You have N boxes & M particles.

$$P_1(n_1) = \frac{\Omega(E_{N-1}, N-1)}{\Omega(E, N)}$$

$$E = \left(n_1 + \frac{1}{2}\right) \hbar \omega + \sum_{i=2}^N \left(n_i + \frac{1}{2}\right) \hbar \omega$$

$$\frac{1}{\hbar \omega} \left[E - \left(n_1 + \frac{1}{2}\right) \hbar \omega \right] = \sum_{i=2}^N n_i + \sum_{i=2}^N \frac{1}{2}$$

$$= M' + \left(\frac{N-1}{2}\right)$$

(M - n₁) particle
and (N - 1) boxes.

$$\frac{E}{\hbar \omega} - \frac{N-1}{2} = \left(n_1 + \frac{1}{2}\right) + M'$$

$$\frac{E}{\hbar \omega} - \frac{N}{2} + \frac{1}{2} - n_1 - \frac{1}{2} = M'$$

$$\boxed{M - n_1 = M'}$$

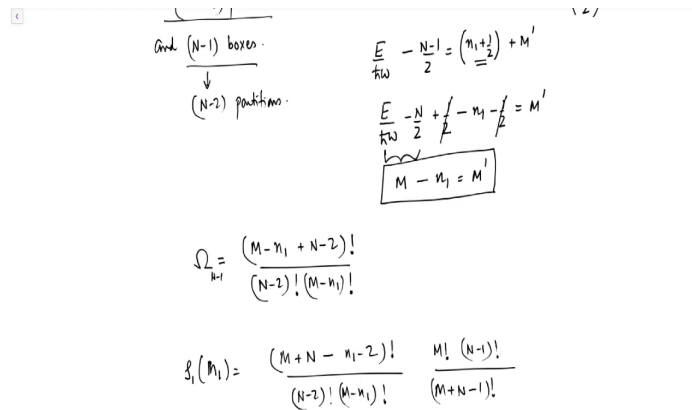

So, let us see instead of writing E divided by h bar omega I have E minus n 1 plus half h bar omega is sum over and then I have 1 over h bar omega is sum over n i plus sum over i equal to 2 to N half of that. And this sum is now 2 to N. So, let us call this sum as M prime plus N minus 1 divided by 2 then, I have E over h bar omega minus N minus 1 by 2 is going to be n 1 plus half plus M prime.

So, we somehow have to relate this with M. If I take look at the left hand side and I have N minus 2 plus half and this one is minus N 1 minus half is going to be your M prime right. Then, you see the half half cancels out and this is already you have defined it as M. So, that you have M minus n 1 as M prime.

So, now what does this mean that if you have I picked up one particular oscillator, then essentially you are left out with M minus n 1 particles and N minus 1 boxes, originally when

you were considering n particles you had N boxes and M particles. Now, if you pick up the n_1 oscillator this occupation number and you want to know the probability density ρ_1 of n_1 then essentially looking at $m - n_1$ particle and $N - 1$ boxes.

(Refer Slide Time: 25:20)

$$\begin{aligned} & \text{And } (N-1) \text{ boxes} \cdot \\ & \quad \downarrow \\ & (N-2) \text{ particles} \cdot \end{aligned}$$

$$\frac{E}{h\nu} = \frac{N-1}{2} = \left(n_1 + \frac{1}{2}\right) + M'$$

$$\frac{E}{h\nu} = \frac{N}{2} + \frac{1}{2} - n_1 - \frac{1}{2} = M'$$

$$\boxed{M - n_1 = M'}$$

$$\Omega = \frac{(M - n_1 + N - 2)!}{(N-2)! (M - n_1)!}$$

$$\rho_1(n_1) = \frac{(M + N - n_1 - 2)!}{(N-2)! (M - n_1)!} \frac{M! (N-1)!}{(M + N - 1)!}$$

So, that you have essentially $N - 2$ partitions. So, therefore, you have $M - N - 1$ the total number of objects is $N - 2$ factorial divided by $N - 2$ factorial and then you have $M - N - 1$ factorial. So, that this is Ω_{N-1} in shorthand notation and therefore, ρ_1 of n_1 is going to be $M - n_1$ so, let us just write it down here $M + N - n_1 - 2$ factorial divided by $N - 2$ factorial $M - n_1$ factorial.

And then we had the original which was $M + N - 1$ factorial and we had M factorial $N - 1$ factorial.

(Refer Slide Time: 26:28)

$$\begin{aligned}
 & \frac{\frac{(M+N-n_1-2)!}{(M+N-1)!} \cdot \frac{M!}{(M-n_1)!} \cdot \frac{(N-1)!}{(N-2)!}}{(M+N-1)(M+N-2)\dots(M+N-n_1-1)(M+N-n_1-2)!} \cdot N \\
 &= \frac{M(M-1)(M-2)\dots(M-n_1+1)}{(M+N-1)(M+N-2)\dots(M+N-n_1-1)} \cdot N \\
 &= \frac{M^{n_1}}{(M+N)^{n_1+1}} \cdot N
 \end{aligned}$$

Now, let us group the terms together so, that it is easier to see what we are going to get M plus N minus n 1 minus 2 factorial divided by M plus N minus 1 factorial and then, I have M factorial M minus N 1 factorial and then I have N 1 factorial N minus 2 factorial. The most trivial of this is the last term, which is going to be N minus 1 and is going to be approximate it by N.

Let us look at this, let us look at the denominator first I have M plus N minus 1 M plus N minus 2 all the way up to M plus N minus n 1 minus 1; and then I have M plus N minus n 1 minus 2 factorial. The numerator is M plus N minus n 1 minus 2 factorial, this term is M M minus 1 M minus 2 all the way up to M minus n 1 plus 1 and then I have M minus n 1 factorial divided by M minus n 1 factorial and of course, I have the last term which is N.

A simplification would mean that this and this cancels out and this and this cancels out. So, that I have $M M^{-1} M^{-2} M^{-n+1} + 1$ divided by $M + N - 1 M + N - 2$ and all the way we are going to $M + N - n + 1$ plus sorry $n - 1$. So, you are almost there, you have to just hold on a little bit more and then I have N .

Now, clearly in the thermodynamic limit what I can do over here is I can have $n - 1$ such terms so, that this is going to be M to the power $n - 1$ and this is going to be $M + N$, there are $n - 1$ such terms is going to be $n - 1$ times N .

(Refer Slide Time: 29:30)

$$\begin{aligned}
 &= \frac{M^{n_1}}{(M+N)^{n_1+1}} \cdot N \\
 \rho_1(n_1) &= \left(\frac{N}{M+N} \right) \left(\frac{M}{M+N} \right)^{n_1} = \frac{1}{1 + \frac{M}{N}} \left(\frac{1}{1 + \frac{N}{M}} \right)^{n_1} \\
 1 + \frac{N}{M} &= e^{\frac{k_0/k_B T}{M}} \\
 \frac{M}{N} &= \left(e^{\frac{k_0/k_B T}{M}} - 1 \right)^{-1} = \\
 \rho_1(n_1) &=
 \end{aligned}$$

So, that ρ_1 of $n - 1$ is going to be N divided by $M + N$ times M over $M + N$ raised to the power $n - 1$. Now, I can recast this as well here this becomes 1 over $1 + M$ over N and this is 1 over $1 + N$ over M raised to the power $n - 1$. Now, if you go back to the lecture on

this quantum oscillator treated micro canonically you will see that $1 + \frac{M}{N}$ was e to the power $\frac{h\bar{\omega}}{k_B T}$.

So, that the this factor is e to the power $\frac{h\bar{\omega}}{k_B T}$ and from this I can write down $\frac{M}{N}$ as e to the power $\frac{h\bar{\omega}}{k_B T}$ minus 1 inverse. So, that I have ρ of $n=1$ is $1 + \dots$ ok.

(Refer Slide Time: 31:12)

$$\frac{M}{N} = \left(e^{-\frac{h\bar{\omega}}{k_B T}} \right)^{-1}$$

$$1 + \frac{M}{N} = 1 + \frac{1}{e^{\frac{h\bar{\omega}}{k_B T} - 1}} = \frac{e^{\frac{h\bar{\omega}}{k_B T}}}{e^{\frac{h\bar{\omega}}{k_B T} - 1}} = \frac{1}{1 - e^{-\frac{h\bar{\omega}}{k_B T}}}$$

$$g_1(n_1) = \frac{1}{(1 - e^{-\frac{h\bar{\omega}}{k_B T}})} e^{-n_1 \frac{h\bar{\omega}}{k_B T}} \leftarrow$$

$$g_1(n) = \frac{1}{1 - e^{-\frac{h\bar{\omega}}{k_B T}}} e^{-n \frac{h\bar{\omega}}{k_B T}}$$

$$g_1(n) = \frac{e^{-\frac{h\bar{\omega}}{k_B T} \cdot \frac{1}{2}}}{e^{\frac{h\bar{\omega}}{k_B T} \cdot \frac{1}{2}} (1 - e^{-\frac{h\bar{\omega}}{k_B T}})} e^{-n \frac{h\bar{\omega}}{k_B T}}$$

We have to take do one more step, I am interested in now $1 + \frac{M}{N}$ which is going to be $1 + e$ to the power $\frac{h\bar{\omega}}{k_B T}$ not e to the power 1 divided by e to the power $\frac{h\bar{\omega}}{k_B T}$ minus 1 and if I do this, it is going to be e to the power $\frac{h\bar{\omega}}{k_B T}$ minus 1. You see the minus 1 in the numerator is going to cancel with this one you will be left out with $\frac{h\bar{\omega}}{k_B T}$, which is nothing but $1 - \dots$ $\frac{h\bar{\omega}}{k_B T}$.

And therefore, $\rho_{1 \text{ of } n \text{ 1}}$ is going to be $1 \text{ over } 1 \text{ minus } \hbar \omega \text{ over } K B T e \text{ to the power minus } n \text{ 1 } \hbar \omega \text{ over } K B T$; and this is essentially the probability that a particle or an oscillator is in the n th quantum level, here of course $n \text{ 1}$ is nothing special so, one can write down $\rho_{1 \text{ of } n}$ as $1 \text{ over } 1 \text{ minus } \hbar \omega \text{ over } K B T e \text{ to the power minus } n \hbar \omega \text{ over } K B T$.

So, now with this expression we can take it a little bit further, let us say I have $\rho_{1 \text{ of } n}$ is going to be $1 \text{ over } I$ want to multiply by $e \text{ to the power minus } \beta \hbar \omega \text{ by } 2$ and divided by or let us say plus and $e \text{ to the power } \beta \hbar \omega \text{ by } 2 \text{ 1 minus } \hbar \omega \text{ over } K B T$; and this becomes $\text{minus } n \hbar \omega \text{ over } K B T$.

(Refer Slide Time: 33:18)

$$\begin{aligned}
 Z_1(n) &= \frac{1}{(1 - e^{-\hbar \omega / k_B T})} e^{-n \hbar \omega / k_B T} \leftarrow \\
 Z_1(n) &= \frac{1}{1 - e^{-\hbar \omega / k_B T}} e^{-n \hbar \omega / k_B T} \\
 \hline
 Z_1(n) &= \frac{e^{-\beta \hbar \omega / 2}}{e^{\beta \hbar \omega / 2} (1 - e^{-\hbar \omega / k_B T})} e^{-n \hbar \omega / k_B T} \\
 &= e^{-\beta (n + \frac{1}{2}) \hbar \omega} \frac{e^{-\beta \hbar \omega / 2}}{1 - e^{-\hbar \omega / k_B T}} \\
 &= e^{-\beta \epsilon_n} \left(\frac{e^{-\beta \hbar \omega / 2}}{1 - e^{-\beta \hbar \omega}} \right) \rightarrow
 \end{aligned}$$

You immediately see that this results in the following simplification the numerator. Now, I can write down $\text{minus } \beta \epsilon_n$, β is $K B T \text{ inverse}$ $n \text{ plus half } \hbar \omega \text{ times } e \text{ to the}$

power minus $\beta \hbar \omega$ over 2 divided by $1 - \hbar \omega / K_B T$. So, that I have e to the power minus $\beta \epsilon_n$ and then, I have e to the power minus $\beta \hbar \omega$ by 2 divided by $1 - \beta \hbar \omega$.

If you see if you recall this is a single particle canonical partition function for single for a harmonic oscillator we have done it explicitly. So, essentially here also it we explicitly showed that you can go from the micro canonical to the canonical probability density.
