Lecture - 43
Free Particle Quantum Canonical Partition Function Free

(Refer Slide Time: 00:22)

Canonical partition of a single particle

Free particle in a box of volume $V=L^3$ with periodic boundary condition.

Momentum representation

$$H = P^2/2m$$
$$H|\psi_k\rangle = E_k|\psi_k\rangle$$

where $E_k = \frac{\hbar^2 k^2}{2m}$

So, we now want to calculate the partition function. Let us say the canonical we will start off with Canonical partition function of a single particle and our first case that we are interested in is a free particle in a box of volume V is equal to L cube with periodic boundary condition right.

So, the task is now very simplified if we look at the momentum representation right. So, in the momentum representation I have the Hamiltonian which is just a single particle is p

square over $2m$ and H of ϕ_k is $E_k \phi_k$, where the energy eigen value is $\hbar^2 k^2$ over $2m$.

(Refer Slide Time: 01:42)

When $E_k = \frac{\hbar^2 k^2}{2m}$

$$\phi_k(r) = \frac{1}{\sqrt{V}} e^{i\vec{k} \cdot \vec{r}}$$

$$\vec{k} = (k_x, k_y, k_z) = \frac{2\pi}{L} (n_x, n_y, n_z)$$

$$\langle \phi_k | \phi_{k'} \rangle = \delta_{\vec{k}, \vec{k}'}$$

$$\sum_k |\phi_k\rangle \langle \phi_k| = \mathbb{1}$$

$$\langle \phi_k | \hat{H} | \phi_{k'} \rangle = \langle \phi_k | \frac{e^{-\beta \hat{H}}}{Z} | \phi_{k'} \rangle$$

$$\delta_{\vec{k}, \vec{k}'} = \frac{e^{-\beta E_k}}{Z} \langle \phi_k | \phi_{k'} \rangle = \frac{e^{-\beta E_k}}{Z} \delta_{\vec{k}, \vec{k}'}$$

The coordinate the wave function the coordinate representation of the wave function I know that it is $i \vec{k} \cdot \vec{r}$ 1 over square root V and this follows from the box normalization where the vector \vec{k} is (k_x, k_y, k_z) which is $\frac{2\pi}{L} (n_x, n_y, n_z)$ right. Now, assuming that this box is large enough, so, these eigen values are typically discrete right and it depends on $1/L$.

So, if $1/L$ is small which means a box is large enough then you can see that these eigen values they lie very very close to each other right. So, you can imagine that. So, you can consider them to be a continuous spectrum of energy eigen values that you have. Now, the

eigen functions are orthonormalized which means $\phi_{k'} \phi_k$ is $\delta_{kk'}$ and they form a complete set right.

So, now I want to calculate the density matrix in this momentum representation and I know how to do that. So, I have essentially $\rho_{k'k}$ which is $\phi_{k'} e^{-\beta H} \phi_k$.

And this is going to be $e^{-\beta E_k} \delta_{kk'}$ which means that this matrix elements are diagonal in this. So, $\rho_{k'k}$ is diagonal in this energy representation which is not very very surprise right.

(Refer Slide Time: 04:08)

$$\rho_{k,k'} = \frac{e^{-\beta E_k} \delta_{k,k'}}{Z}$$

Partition Function $\text{Tr}(\rho) = 1$

$$Z = \sum_k e^{-\beta E_k} = \sum_k e^{-\beta \hbar^2 k^2 / 2m}$$

$$Z(T, V, \mu) = \frac{V}{(2\pi)^3} \int d^3k e^{-\beta \hbar^2 k^2 / 2m} = \left(\frac{V}{\lambda_T^3} \right)$$

$\lambda_T \equiv \frac{2\pi \hbar}{\sqrt{2m k_B T}}$

$n_x, n_y, n_z \sim \left(\frac{2\pi}{L}\right)^3$

appearance $\frac{1}{\lambda_T^3}$ happens quite naturally.

So, therefore, the partition function follows from trace of rho is equal to 1 that is the normalization condition and one gets therefore, Z is equal to sum over k $e^{-\beta E_k}$ which is sum over k $e^{-\beta \frac{\hbar^2 k^2}{2m}}$.

Now, up to this is fine, but now in order to evaluate the sum I realize that this vector k is equal to $2\pi/L$ n_x , n_y and n_z discrete values, but it goes as $1/L$. So, clearly if I have a large box that I am considering then this energy values are spaced very very closely. So, one can imagine that for a large box I have a continuous spectrum of energy value.

So, since the energy values are very very closely packed I can convert this into integral. I will write down Z as explicitly $Z(T, V, 1)$, I have just one particle and this is going to be $V / (2\pi)^3$ whole cube. This discrete sum gets converted into this into d^3k $e^{-\beta \frac{\hbar^2 k^2}{2m}}$.

This you can realize this conversion happens because you know that in let us say you take x direction then n_x and between n_x plus 1 there is only one mode. So, $2\pi/L$ contains only one mode right. So, therefore, from that conversion you see that this is in three dimensions this is going to be $(2\pi)^3$ whole cube over L^3 .

So, that is $(2\pi)^3$ whole cube over V this has only one mode therefore, this integral comes out to be if you go from the sum to an integral you are going to use this. And if you do the integral it is not very difficult to do you are going to get V / λ^3 , which is exactly the classical partition function for a single particle that we had evaluated.

However, the difference is here λ^3 will naturally appear and λ^3 contains \hbar . So, the appearance of \hbar happens quite naturally, it is not introduced in any ad-hoc manner that you can imagine, it is appears because of this form of integral that is it. In classical statistical mechanics we had to kind of introduce it rather ad-hocly saying that well my micro number partition function I am going to take a look of that.

Therefore, Z must be dimensionless, but for such a system hydrostatic system or even for a single particle free particle I know that the partition function is an integral over momentum and coordinates. Therefore, it is dimension full and therefore, I divided by $2\pi\hbar$ because p and q are p times q has a dimension of action and \hbar also has the dimension of action right, good.

(Refer Slide Time: 07:35)

⏪
"I quite naturally."

$$\rho_{k,k'} = \frac{1}{V} e^{-\beta\hbar^2 k^2/2m} \delta_{k,k'}$$

$$\begin{aligned} \langle \vec{r}' | \hat{\rho} | \vec{r} \rangle &= \sum_{k,k'} \langle \vec{r}' | \phi_k \rangle \langle \phi_k | \hat{\rho} | \phi_{k'} \rangle \langle \phi_{k'} | \vec{r} \rangle \\ &= \sum_{k,k'} \langle \vec{r}' | \phi_k \rangle \left(\frac{1}{V} e^{-\beta E_k} \right) \delta_{k,k'} \langle \phi_{k'} | \vec{r} \rangle \\ &= \sum_k \langle \vec{r}' | \phi_k \rangle \frac{1}{V} e^{-\beta E_k} \langle \phi_k | \vec{r} \rangle \end{aligned}$$

$$\langle \phi_k | \vec{r} \rangle = \frac{1}{\sqrt{V}} e^{i\vec{k}\cdot\vec{r}}$$

But now so, essentially therefore, I have $\rho_{k,k'} = \frac{1}{V} e^{-\beta\hbar^2 k^2/2m} \delta_{k,k'}$. Now, the idea is that I want to evaluate the same density matrix in the coordinate representation. So, in the coordinate representation would mean that I have \vec{r}' and then I have \vec{r} .

So, this I can write down k to I will write down \vec{r}' ϕ_k ϕ_k ρ ϕ_k ϕ_k \vec{r} . So, I introduce the completeness of this and this quantity I already know right.

This quantity is at least this quantity I know is k k prime r prime $\phi_k e$ to the power minus βE_k we will just use that $1/z$ or rather let us explicitly use it λT sorry.

So, many stupid mistakes λT over $V e$ to the power minus β it is a $k E_k \delta_k$ comma k prime and then I have ϕ of k prime r . So, I can carry over ones sum over k and take care of the delta function. So, that I am going to have sum over k r prime $\phi_k \lambda T$ over $V e$ to the power minus $\beta E_k \phi_k$ times r right. Now, ϕ_k is minus $i k \cdot r$ 1 over square root V .

(Refer Slide Time: 10:01)

$$\begin{aligned}
 \langle \phi_k | \bar{r} \rangle &= \frac{1}{\sqrt{V}} e^{i\vec{k} \cdot \bar{r}} \\
 \langle \bar{r} | \phi_k \rangle &= \frac{1}{\sqrt{V}} e^{-i\vec{k} \cdot \bar{r}} \\
 &= \sum_k \langle \bar{r} | \phi_k \rangle \frac{\lambda T}{V} e^{-\beta E_k} \langle \phi_k | \bar{r} \rangle \\
 &= \frac{\lambda T}{V} \frac{1}{(2\pi)^3} \int d^3k \frac{1}{\sqrt{V}} e^{i\vec{k} \cdot \bar{r}'} e^{-\beta E_k} \frac{1}{\sqrt{V}} e^{-i\vec{k} \cdot \bar{r}} \\
 &= \frac{\lambda T}{V} \frac{1}{(2\pi)^3} \int d^3k \frac{e^{-\beta \hbar^2 k^2 / 2m - i\vec{k} \cdot (\bar{r} - \bar{r}')}}{e} \\
 -\beta \hbar^2 \frac{k^2}{2m} + i\vec{k} \cdot (\bar{r}' - \bar{r}) &= -\frac{\beta \hbar^2}{2m} \left[k^2 - \frac{2m i}{\beta \hbar^2} \vec{k} \cdot (\bar{r}' - \bar{r}) \right] \\
 &= -\frac{\beta \hbar^2}{2m} \left[\dots \right]
 \end{aligned}$$

And ϕ_k is 1 over square root $V e$ to the power $i k \cdot r$ right. So, that this sum is sum over k ; so, I have λT over V times the sum becomes an integral d cube of $k e$ to the power $i k \cdot r$ prime 1 over square root $V e$ to the power minus βE_k and then I have 1 over square root of $V e$ to the minus $i k \cdot r$ right.

So, you see all of this I have a factor V then I have 1 over V here. This, this cancels square root V square root V gives me a V. So, I have 1 over lambda. So, lambda T over V integral d cube of k e to the power minus beta h square k square over twice m e to the power i k minus i k dot r minus r prime.

Let us look at the argument of the exponential. I have minus beta h bar square k square over twice m plus i k dot r prime minus r which I take it as minus beta h square over twice m k square minus 2m twice mi over beta h bar square k dot r prime minus r.

(Refer Slide Time: 12:31)

$$\begin{aligned}
 -\frac{\beta \hbar^2 k^2}{2m} + i\vec{k} \cdot (\vec{r}' - \vec{r}) &= -\frac{\beta \hbar^2}{2m} \left[k^2 - \frac{2mi}{\beta \hbar^2} \vec{k} \cdot (\vec{r}' - \vec{r}) \right] \\
 &= -\frac{\beta \hbar^2}{2m} \left[k^2 - \frac{2mi}{\beta \hbar^2} \vec{k} \cdot (\vec{r}' - \vec{r}) + \left(\frac{mi}{\beta \hbar^2} \right)^2 (\vec{r}' - \vec{r})^2 \right] \\
 &\quad + \left(\frac{mi}{\beta \hbar^2} \right)^2 (\vec{r}' - \vec{r})^2 \frac{\beta \hbar^2}{2m} \\
 &= -\frac{\beta \hbar^2}{2m} (\vec{k} - \vec{k}_0)^2 - \frac{m^2 \beta \hbar^2}{2m} (\vec{r}' - \vec{r})^2 \\
 &= -\frac{\beta \hbar^2}{2m} (\vec{k} - \vec{k}_0)^2 - \frac{m}{2\beta \hbar^2} (\vec{r}' - \vec{r})^2
 \end{aligned}$$

Which is minus beta h bar square this is the standard manipulation of a Gaussian integral and k square minus twice m i beta h bar square k dot r prime minus r plus m i beta h bar square whole square r prime minus r. So, that this argument becomes a complete square and then you

are adding this term you have to subtract m over $\beta \hbar^2$ whole square $r' - r$ whole square times $\beta \hbar^2$ square twice m .

So, therefore, this integral, so, this becomes k square. So, we will write down straightforward as $k - k_0$ whole square, this gives you an i square as minus right. So, this is going to be (Refer Time: 13:38) one has to be careful over here. This gives you an i square, i square is minus 1 and then there is overall minus.

So, this becomes a plus and therefore, this is going to be minus m square β square \hbar^4 $\beta \hbar^2$ square twice m $r' - r$ whole square. So, this becomes minus over twice m $k - k_0$ whole square. I cancel with the m , one β goes out, one \hbar square goes out. So, I have $m \beta \hbar^2$ half $r' - r$ whole square. So, it will be involved algebra, but nothing which you cannot do; nothing which is not do able.

(Refer Slide Time: 14:44)

$$\begin{aligned}
 \langle \vec{r}' | \hat{g} | \vec{r} \rangle &= \frac{\Lambda_T}{V} \frac{1}{(2\pi)^3} \int_{\vec{k}} e^{-\frac{\beta \hbar^2}{2m} (\vec{k} - \vec{k}_0)^2} e^{-\frac{m}{2\beta \hbar^2} (\vec{r}' - \vec{r})^2} \\
 &= \frac{\Lambda_T}{V} \frac{1}{(2\pi)^3} \left(\frac{2m\pi}{\beta \hbar^2} \right)^{3/2} e^{-\frac{\beta \hbar^2}{2m} (\vec{r}' - \vec{r})^2} \\
 &= \left[\frac{\Lambda_T}{V} \right]^{3/2} \frac{1}{\Lambda_T} \left(\frac{m\pi}{\beta \hbar^2} \right)^{3/2} = \left(\frac{m\kappa_B T}{2\pi \hbar^2} \right)^{3/2} \frac{1}{\Lambda_T}
 \end{aligned}$$

$\vec{k}_0 = \frac{m i}{\beta \hbar^2} (\vec{r}' - \vec{r})$
 $\Lambda_T \sim \beta^{3/2}$
 $\lambda_T^3 = \Lambda_T$

So, your integral over here now is very nicely, your the matrix in the coordinate representation the density matrix now takes the form as λT over $V \frac{1}{2\pi}$ whole cube integral $d^3k e$ to the power minus $\beta \hbar^2$ over twice $m k^2$ minus k^2 naught.

And note that k^2 naught is m^2 over $\beta \hbar^2$ square r^2 prime minus r^2 right; whole square times e to the power minus m^2 over $2\beta \hbar^2$ whole square r^2 prime minus r^2 whole square. Now, this integral is exactly doable, now it is in a Gaussian form and note that this measure is actually k^2 square dK .

And if you evaluate this integral, so, this is just square root π by a for one dimension I know, but this is now k^2 square multiply, therefore, this is going to be twice π whole cube. You are going to get $2m \pi$ over $\beta \hbar^2$ square raise to the power $3/2$ times e to the power minus $\beta 2m \hbar^2$ square r^2 prime minus r^2 whole square.

Now of course, it involves certain limit of amount of algebra. If you carefully look at this then this is just 1 over λT right. Just simplify this then you will see that this is going to be 1 over λT and this quantity that you see over here is going to be λT where λT whole cube is going to be capital λT .

So, just simplify this. This becomes twice $m \pi$ over $\beta \hbar^2$ square and this term I can write 2π whole square times raise to the power $3/2$. So, this becomes $4\pi^2$ square raise to the power $3/2$ and this is very easy to calculate now.

Beta takes a $k_B T$, $m k_B T$ and then you have this gives you 2 , this gives you π . $2\pi \hbar^2$ square raise to the power $3/2$ which is exactly your 1 by λT , right. Recall in the classical statistical mechanics when we did calculate your define this de Broglie wave length, we said that this quantity goes as beta to the power d by ν . In our case it is beta to the power $3/2$ and therefore, you have this as 1 over λT .

(Refer Slide Time: 17:45)

$$\begin{aligned}
 \langle \vec{r}' | \hat{\rho} | \vec{r} \rangle &= \frac{\lambda_T}{V} \frac{1}{(2\pi)^3} \int d^3k e^{i\vec{k}\cdot\vec{r}'} e^{-i\vec{k}\cdot\vec{r}} e^{-\frac{\beta}{2mk_B}(\vec{r}'-\vec{r})^2} \quad \lambda_T \sim T \\
 &= \frac{\lambda_T}{V} \frac{1}{(2\pi)^3} \left(\frac{2m\pi}{\beta k^2} \right)^{3/2} e^{-\frac{\beta}{2mk_B}(\vec{r}'-\vec{r})^2} \quad \lambda_T^3 = \lambda_T \\
 &\quad \left[\frac{1}{(2\pi)^3} \right]^{3/2} \frac{1}{\lambda_T} \left(\frac{2m\pi}{\beta k^2} \right)^{3/2} = \left(\frac{mk_B T}{2\pi k^2} \right)^{3/2} \equiv \frac{1}{\lambda_T} \\
 &= \frac{\lambda_T}{V} \frac{1}{\lambda_T} e^{-\pi(\vec{r}'-\vec{r})^2/\lambda_T^2} \quad \lambda_T^3 = \lambda_T \\
 &\quad \pi(\vec{r}'-\vec{r})^2/\lambda_T^2 \quad \lambda_T = \lambda_T^{1/3} \\
 \langle \vec{r}' | \hat{\rho} | \vec{r} \rangle &= \frac{1}{V} e^{-\pi(\vec{r}'-\vec{r})^2/\lambda_T^2}
 \end{aligned}$$

And if you look at this quantity this becomes pi times lambda T square and therefore, this is lambda T over V 1 over lambda T e to the power minus pi r prime minus r whole square divided by lambda T square where lambda T whole cube is equal to capital lambda T and lambda T is lambda T raise to the power one-third; capital lambda T raise to the power one-third.

So, that the expression for the density matrix in the coordinate representation takes a very neat form, which is 1 by V e to the power minus pi r prime minus r whole square divided by lambda T square.

(Refer Slide Time: 18:32)

$$\langle \vec{r}' | \hat{\rho} | \vec{r} \rangle = \frac{1}{V} e^{-\lambda_T |\vec{r}' - \vec{r}|^2}$$

$\langle \vec{r}' | \hat{\rho} | \vec{r} \rangle = \frac{1}{V}$
 $\lambda_T \sim \beta^{1/\nu}$

off diagonal elements of $\hat{\rho}$ $\langle \vec{r}' | \hat{\rho} | \vec{r} \rangle$ transition probability from $|\vec{r}\rangle$ to $|\vec{r}'\rangle$

$T \rightarrow \infty$	$\lambda_T \rightarrow 0$
$T \rightarrow 0$	$\lambda_T \rightarrow \infty$

Now, if you look at it carefully then you see that the diagonal elements, which is ρ_{rr} is equal to $1/V$. And this quantity so, one particle in a volume V and this quantity is nothing but the classical density is a classical density. The transition this off diagonal elements denote the transition probability from r to r' and these are your off diagonal elements of ρ in the coordinate presentation.

Now, as T tends to infinity, you know that λ_T goes to zero because λ_T goes as $\beta^{-1/\nu}$. So, in the limit of this when λ_T in the limit of large temperature, when λ_T vanishes you see the off diagonal elements of this also vanish right. So, you only have the coordinate you only have the diagonal elements. When T tends to 0, your λ_T tends to infinity and that is when your off diagonal elements starts appearing and you talk about a transition probability from r to r' .

(Refer Slide Time: 20:10)

Free particle in a box

↓

$\langle \phi_{k'} | \hat{\rho} | \phi_k \rangle$ $\langle \vec{r}' | \hat{\rho} | \vec{r} \rangle$

$$\langle E \rangle = \text{Tr}(\hat{\rho} \hat{K}) = \sum_{\vec{k}, \vec{k}'} \langle \vec{k}' | \hat{\rho} | \vec{k} \rangle \langle \vec{k}' | \hat{K} | \vec{k} \rangle$$

$$= \sum_{\vec{k}, \vec{k}'} \frac{e^{-\beta \hbar^2 \vec{k}^2 / 2m}}{Z} \frac{\hbar^2 \vec{k}^2}{2m} \delta_{\vec{k}', \vec{k}}$$

$$= \frac{1}{Z} \sum_{\vec{k}} e^{-\beta \hbar^2 \vec{k}^2 / 2m} \frac{\hbar^2 \vec{k}^2}{2m}$$

So, we have looked at the ideal gas, free particle in a box and for this particular case we computed the density matrix in the momentum representation as well as in the coordinate representation. So, we calculated $\phi_k \phi_{k'}$ as well as $r' \rho \hat{r}$. Note that this representation ϕ_k is identical to this presentation and we will use this interchanging.

So, the average energy is given by trace of $\hat{\rho} \hat{H}$ which is going to be sum over k prime k $\rho \hat{H} k$ and this is e to the power minus sum over k k prime and there is a vector sign on top. Since we are looking at three dimensional system, $\hbar^2 k^2$ over $2m$.

The Hamiltonian is $\hbar^2 k^2$ over twice m and I have a Z which comes from ρ and I have $\delta_{k' K}$. So, I can use one of the sums to take care of the delta function and I

have $1/Z$ e to the power minus $\beta \hbar^2 k^2 / 2m$ over twice $m \hbar^2 k^2$ square over twice m .

(Refer Slide Time: 22:08)

$$\begin{aligned}
 \langle E \rangle &= \text{Tr}(\hat{p} \hat{K}) = \sum_{\vec{k}, \vec{k}'} \langle \vec{k} | \hat{p} | \vec{k}' \rangle \langle \vec{k}' | X | \vec{k} \rangle \\
 &= \sum_{\vec{k}, \vec{k}'} \frac{e^{-\beta \hbar^2 \vec{k}'^2 / 2m}}{Z} \frac{\hbar^2 \vec{k}'^2}{2m} \delta_{\vec{k}', \vec{k}} \\
 &= \frac{1}{Z} \sum_{\vec{k}} e^{-\beta \hbar^2 \vec{k}^2 / 2m} \frac{\hbar^2 \vec{k}^2}{2m} \\
 &= \frac{\Lambda_T}{V} \frac{V}{(2\pi)^3} \int d^3k \left(\frac{\hbar^2 \vec{k}^2}{2m} \right) e^{-\beta \hbar^2 \vec{k}^2 / 2m} \\
 &= \frac{\Lambda_T}{V} \frac{V}{(2\pi)^3} \int d^3k k^2 e^{-\beta \hbar^2 \vec{k}^2 / 2m}
 \end{aligned}$$

$Z = \frac{V}{\Lambda_T}$

This I know that the single particle partition function is V over the λT . So, this becomes λT over V . The integral over k can be again converted d^3 of k and I have $\hbar^2 k^2$ over twice m times e to the power minus $\beta \hbar^2 k^2$ over twice m .

So, which means, I have λT over V , V over 2π whole cube \hbar^2 over twice m d^3k , this gives me a factor k^2 and there is already a factor k^2 . So, this is e to the power minus $\beta \hbar^2 k^2$ over twice m .

(Refer Slide Time: 23:01)

$$\begin{aligned}
 &= \frac{\lambda T}{V} \frac{V}{(2\pi)^3} \int \left(\frac{\hbar^2 k^2}{2m}\right) e^{-\beta \hbar^2 k^2 / 2m} \\
 &= \frac{\lambda T}{V} \frac{V}{(2\pi)^3} \int k dk k^3 e^{-\beta \hbar^2 k^2 / 2m} \quad \left\{ \begin{array}{l} k^3 = \left(\frac{2mX}{\hbar^2}\right)^{3/2} \\ x = \frac{\beta \hbar^2 k^2}{2m} \end{array} \right. \\
 \langle E \rangle &= \frac{\lambda T}{V} \frac{V}{(2\pi)^3} \left(\frac{\hbar^2}{2m}\right) \int \frac{m dx}{\beta \hbar^2} \left(\frac{2mX}{\beta \hbar^2}\right)^{3/2} e^{-X} \quad \left\{ \begin{array}{l} dx = \frac{\beta \hbar^2}{2m} 2k dk \\ k dk = \frac{m}{\beta \hbar^2} dx \end{array} \right. \\
 &= \frac{\lambda T}{V} \frac{V}{(2\pi)^3} \frac{\hbar^2}{2m} \frac{m}{\beta \hbar^2} \left(\frac{2m}{\beta \hbar^2}\right)^{3/2} \int dx \frac{3}{2} e^{-X} \\
 \boxed{\langle E \rangle} &= \frac{3}{2} k_B T
 \end{aligned}$$

If you substitute x as $\beta \hbar^2 k^2 / 2m$ then dx is $\beta \hbar^2 k dk$. So, that $k dk$ is going to be $m / \beta \hbar^2 dx$. So, average of the energy is going to be $\lambda T / V$, $V / (2\pi)^3 \hbar^2 / 2m$.

So, I can use it as $k dk$ times k^3 . So, we will just write it down as k times dk times k^3 and $k dk$ is $m / \beta \hbar^2 dx$. From this relation substitution I know that k is going to be $\sqrt{2mX / \beta \hbar^2}$. So, raise to the power half. So, k^3 is going to be this raise to the power $3/2$. So, I have $2mX / \beta \hbar^2$ raise to the power $3/2$ e^{-X} .

So, everything comes out now. The $\lambda T V$, V over 2π whole cube \hbar square over twice m , m over $\beta \hbar$ square and then I have twice $m \beta \hbar$ square raise to the power $3/2$. I have dx to the power $3/2$ e to the power minus X .

This I can express it in terms of a gamma function and is going to be and will give me a square root π . So, if I now simplify this V , V is going to cancel out, all these factor if you simplify you will finally, get that this is going to come out to be $3/2 k_B T$ in accordance to the classical result.
