Lecture - 51
Degenerate Fermi Gas

(Refer Slide Time: 00:18)

Degenerate Fermi Gas \rightarrow At $T=0$.

$$\langle n_{\vec{k}} \rangle = \frac{1}{z^{-1} e^{\beta \epsilon_{\vec{k}}} - 1}$$

So, we now specifically look at the Degenerate Fermi Gas and that is an ideal fermi gas at the temperature T is equal to 0. Now, the average occupation number $n_{\vec{k}}$ is given by 1 over Z inverse e to the power $\beta \epsilon_{\vec{k}}$ minus 1 right.

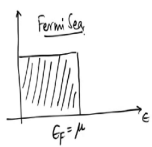

(Refer Slide Time: 00:50)

$$\langle n_{\vec{k}} \rangle = \frac{1}{e^{\beta(\epsilon_{\vec{k}} - \mu)} + 1}$$

$$\langle n_{\vec{k}} \rangle = 1 \quad \epsilon_{\vec{k}} \leq \mu$$

$$= 0$$

$\epsilon_{\vec{k}} < \mu$ $\epsilon_{\vec{k}} > \mu$
 $(\epsilon_{\vec{k}} - \mu)$ $T \rightarrow 0$
 $\beta \rightarrow \infty$
 $\frac{1}{e^{\beta(\epsilon_{\vec{k}} - \mu)}}$
 $\epsilon_{\vec{k}} = \mu$ $\epsilon_F = \mu$
 $\epsilon_{\vec{k}} = \frac{\hbar^2 k^2}{2m}$

The average occupation number is given by $n_{\vec{k}}$ is equal to $1 / (e^{\beta(\epsilon_{\vec{k}} - \mu)} + 1)$. So, now, we have to figure this out at $T = 0$, but one has to be careful with this. Because you see that if $\epsilon_{\vec{k}}$ is less than μ , then this term $\epsilon_{\vec{k}} - \mu$ is negative.

So, that this term is actually $1 / e^{\beta(\epsilon_{\vec{k}} - \mu)}$ right. And in the limit of $T \rightarrow 0$ or exactly at $T = 0$, β is infinity. So, that this term vanishes and therefore, you have average occupation number is equal to 1 for all energy levels $\epsilon_{\vec{k}}$ which are less than equal to μ .

So, similar argument when $\epsilon_{\vec{k}}$ is greater than μ , then you see that this term is positive and the denominator itself it becomes infinitely large and therefore, you get a 0. So, if you want to plot the occupation number as a function of the energy level, then you will see that all

the levels up to this chemical potential μ are completely filled at T equal to 0 right and this completely filled levels define my Fermi Sea.

So, this defines my Fermi Sea. All energy levels up to ϵ_k is equal to μ are completely filled at T equal to 0 and therefore, at T equal to 0, the fermi energy equals to the chemical potential of the system. Now, since I am looking at a ideal gas, where ϵ_k is equal to $\frac{\hbar^2 k^2}{2m}$, I can define a fermi wave vector.

(Refer Slide Time: 03:10)

The slide contains a diagram and several equations. The diagram shows a shaded rectangular region in the energy ϵ vs. wave vector k plane, labeled "Fermi Sea". The energy axis is marked with $\epsilon_F = \mu$. To the right, there are handwritten notes: $\epsilon_k = \mu$ (circled), $\epsilon_k = \frac{\hbar^2 k^2}{2m}$ (circled), and k_F (circled). Below the diagram, the following equations are written:

$$N = \sum_{\vec{k}} \langle n_{\vec{k}} \rangle = \frac{gV}{(2\pi)^3} \int_0^{k_F} 4\pi k^2 dk \langle n_{\vec{k}} \rangle$$

$$= \frac{gV}{2\pi^2} \int_0^{k_F} k^2 dk = \frac{gV}{2\pi^2} \frac{k_F^3}{3}$$

$$\Rightarrow k_F^3 = \frac{6\pi^2}{g} \frac{N}{V} = \frac{6\pi^2 \hbar^3}{g}$$

$$k_F = \left(\frac{6\pi^2 n}{g} \right)^{1/3}$$

At the bottom left is the NPTEL logo, and at the bottom right is a small video inset of a man in a blue shirt.

Now, to define the fermi wave vector, I note that total number of particles is sum over k average of n_k right and the sum over k , I know is $\frac{gV}{(2\pi)^3} \int_0^\infty 4\pi k^2 dk$ right and this goes from 0 to infinity and then, I have n_k but n_k .

So, the idea is to determine define a fermi vector, k_F corresponding to this fermi energy ϵ_f and therefore, n_k is 1, only up to this fermi vector k_F . So, one has gV as 2π . This is going to be 2π square 0 to k_F k square $d k$ because beyond that beyond this value of k_F , the average occupation number is 0.

So, this quantity becomes gV over 2π square k_F cube over 3. You immediately see that this implies that k_F cube is going to be 6π square over g times N over V which is 6π square the number density n divided by the g . So, that k_F is 6π square n over g raised to the power one-third.

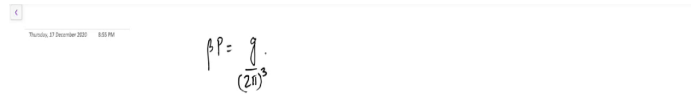

(Refer Slide Time: 04:50)

$$\begin{aligned}
 N = \sum_{\mathbf{k}} \langle n_{\mathbf{k}} \rangle &= \frac{gV}{(2\pi)^3} \int_0^{k_F} 4\pi k^2 dk \langle n_{\mathbf{k}} \rangle \\
 &= \frac{gV}{2\pi^2} \int_0^{k_F} k^2 dk = \frac{gV}{2\pi^2} \frac{k_F^3}{3} \\
 \Rightarrow k_F^3 &= \frac{6\pi^2 N}{gV} = \frac{6\pi^2 n}{g} \\
 k_F &= \left(\frac{6\pi^2 n}{g} \right)^{1/3} \rightarrow \text{Fermi wave vector.} \\
 \epsilon_F = \frac{\hbar^2 k_F^2}{2m} &= \frac{\hbar^2}{2m} \left(\frac{6\pi^2 n}{g} \right)^{2/3} = \mu
 \end{aligned}$$

So, this defines my Fermi Wave vector. And the fermi energy which is ϵ_F is $\frac{\hbar^2 k_F^2}{2m}$ is given by $\frac{\hbar^2}{2m} \left(\frac{6\pi^2 n}{g} \right)^{2/3}$ and this is the chemical potential at 0 temperature.

(Refer Slide Time: 05:34)

The slide displays the equation $\beta P = \frac{g}{(2\pi)^3}$. Above the equation, there is a small window with a close button and the text "Physics 17 December 2022 8:58 PM".

So, let us look at the thermodynamic pressure. The thermodynamic pressure, we have been looking at this expression. So, many times this was g over 2π whole cube or rather if I just take care of things, it is going to be $\eta + 1$.

(Refer Slide Time: 05:48)

$$\begin{aligned}
 p_1 &= \frac{g}{2\pi^2} \int_0^\infty k^2 dk \ln \left(1 + Z e^{-\beta \epsilon_k} \right) \\
 &= \frac{g}{2\pi^2} \left[\ln \left(1 + Z e^{-\beta \epsilon_k} \right) \frac{k^3}{3} \right]_0^\infty - \int_0^\infty dk \frac{k^3}{3} \frac{\left(Z e^{-\beta \epsilon_k} \right)}{1 + Z e^{-\beta \epsilon_k}} \left(-\beta \frac{d\epsilon_k}{dk} \right) \\
 &= \frac{g}{2\pi^2} \frac{1}{3} \int_0^\infty dk k^3 \frac{d\epsilon_k}{dk} \frac{1}{Z e^{-\beta \epsilon_k} + 1} \\
 &= \frac{g}{2\pi^2} \frac{1}{3} \int_0^\infty dk k^3 \frac{d\epsilon_k}{dk} \langle n_k \rangle
 \end{aligned}$$

So, this is going to be g over 2π square integral k square $dk \ln 1$ plus $Z e$ to the power minus $\beta \epsilon_k$. Now, this I can manipulate and write down as integration. So, let us say this is 0 to infinity; this is going to be dk . Choose this as the first function, then you have \ln , there is no dk over here in the first term, when you integrate by parts, it is going to be $\ln 1$ plus $Z e$ to the power minus $\beta \epsilon_k$.

Of course, it is a function of k . So, we can still keep that over here k cube by 3 , 0 to infinity minus this is going to be integration 0 to infinity dk . I will have k cube by 3 and then, derivative of this log with respect to k . So, that takes me 1 plus $Z e$ to the power minus $\beta \epsilon_k$ k and then, I have $Z e$ to the power minus $\beta \epsilon_k$ k times minus of $\beta \frac{d\epsilon_k}{dk}$.

Well, it is a $\frac{g\beta}{2\pi^2} \int_0^\infty dk k^3 \frac{d\epsilon_k}{dk} \langle n_k \rangle$; $\frac{g\beta}{2\pi^2} \int_0^\infty dk k^3$ right. So, this term is going to vanish. So, that you will be left out with $\frac{g\beta}{2\pi^2}$; the minus and minus is going to give you a plus; the beta comes out and you are left out with $\int_0^\infty dk k^3$ and this is $\frac{1}{3} k^4$.

So, this is going to be $\frac{g\beta}{2\pi^2} \int_0^\infty dk k^3$ times $\frac{1}{3} k^4$ inverse ϵ to the power beta ϵ_k plus 1. And if you carefully look at this, then this is nothing but the average expectation value; $\langle n_k \rangle$ sorry, it's nothing but the average occupation number. So, that you have $\frac{g\beta}{2\pi^2} \int_0^\infty dk k^3$ average of n_k .

(Refer Slide Time: 08:31)

$$\begin{aligned}
 & \langle n_k \rangle = \theta(k - k_F) \\
 & = \frac{g\beta}{2\pi^2} \frac{1}{3} \int_0^\infty dk k^3 \frac{d\epsilon_k}{dk} \langle n_k \rangle \quad \frac{d\epsilon_k}{dk} = \frac{\hbar^2 k}{m} \\
 & = \frac{g\beta}{2\pi^2} \frac{1}{3} \frac{\hbar^2}{m} \int_0^{k_F} dk k^4 = \frac{g\beta}{2\pi^2} \frac{\hbar^2}{15m} k_F^5 \quad k_F = \left(\frac{6n}{g}\right)^{1/3} \\
 & = \frac{g\beta}{2\pi^2} \frac{\hbar^2}{15m} \left(\frac{6n}{g}\right)^{5/3} \quad \epsilon_F = \frac{\hbar^2 k_F^2}{2m} = \mu \\
 & \quad k_F = \left(\frac{2m}{\hbar^2}\right)^{1/2} \mu^{1/2} \\
 \beta P & = \frac{g\beta}{2\pi^2} \frac{\hbar^2}{15m} \left(\frac{2m}{\hbar^2}\right)^{5/2} \mu^{5/2}
 \end{aligned}$$

Now, the average of the occupation number at 0 temperature has the form $\theta(k - k_F)$; where θ is the heavy side function. So, that this expression is $\frac{g\beta}{2\pi^2} \int_0^\infty dk k^3$ is going to be $\frac{\hbar^2}{2m} k^2$. So, that I have $\frac{\hbar^2}{2m} k^2$ square over m integral 0 to k_F dk , k to the power 4 which is $\frac{g\beta}{2\pi^2}$. I am

going to have h^2 over $15m$ times k_F to the power 5 and now, k_F is $6\pi^2 n$ over g raised to the power $1/3$. So, that I have g beta over twice π^2 h^2 over $15m$ and then, I have $6\pi^2 n$ over g raised to the power of $5/3$.

Now, I also know that ϵ_F is going to be $h^2 k_F^2$ over twice m which is going to be μ at 0 temperature. So, I can equally write down twice m over $h^2 k_F^2$ and μ to the power half. So, this expression, I can also write down as g beta over twice π^2 h^2 over $15m$ times twice m over $h^2 k_F^2$ raised to the power $5/2$ and μ to the power $5/2$. So, you see the beta P has this expression.

(Refer Slide Time: 10:39)

The slide contains several handwritten equations:

- Top left:
$$= \frac{gV}{2\pi^2} \frac{k^2}{15m} \left(\frac{6\pi^2 n}{g}\right)^{5/3}$$
- Top right:
$$\epsilon_F = \frac{\hbar^2 k_F^2}{2m} = \mu$$

$$k_F = \left(\frac{2m}{\hbar^2}\right)^{1/2} \mu^{1/2}$$
- Center (boxed):
$$P = \frac{g}{2\pi^2} \frac{\hbar^2}{15m} \left(\frac{2m}{\hbar^2}\right)^{5/2} \mu^{5/2}$$
- Below center:
$$E = \sum_k \epsilon_F \langle n_k \rangle = \frac{gV}{2\pi^2} \int k^2 dk \frac{\hbar^2 k^2}{2m} \langle n_k \rangle$$

$$= \frac{gV}{2\pi^2} \frac{\hbar^2}{2m} \frac{k_F^5}{5} = \frac{gV}{(2\pi^2)^2} \frac{\hbar^2}{10m} \left(\frac{2m}{\hbar^2}\right)^{5/2} \mu^{5/2}$$
- Bottom left (boxed):
$$P = \frac{3}{2} \frac{E}{V}$$
 Handwritten

Now, beta beta is going to cancel out from both side right. What about the energy? Energy was sum over k ϵ_F n_k which I know as gV over $2\pi^2$ k^2 dk h^2 square k square over twice m . So, sorry there is an average occupation over here and n_k .

So, this is going to be $g V$ over $2 \pi^2 \hbar^3$ over $2 m$ and I am going to have $k_B T$ to the power $5/2$ right and once again, this is going to be just $g V$ in terms of the chemical potential, the energy is going to be $2 \pi^2 \hbar^3$ over $2 m$.

And I am going to have $2 n$ by \hbar^3 raised to the power $5/2$ ν to the power $5/2$ and there is going to be a this factor is going to be $10, 5$ multiplied by 2 ; this factor is 15 and this factor is 10 and you immediately realize that pressure is $2/3$ by sorry pressure is $3/2$ times E/V which is the usual case that for a non relativistic gas and which we derived very generally in our earlier classes.
