Lecture - 55
Bose-Einstein Condensation

(Refer Slide Time: 00:19)

$$\left(\frac{2\pi m V}{h^3} \right)^{3/2} = g V \left(\frac{2m\pi}{\beta h^2} \right)^{3/2} = \frac{g V}{\lambda_T^3}$$

$$N = \frac{g V}{\lambda_T^3} \int_{3/2}^{\infty} g(\epsilon) + \frac{g Z}{1-Z}$$

$$N = \frac{g V}{\lambda_T^3} \int_{3/2}^{\infty} g(\epsilon) + N_0(\epsilon)$$

$$f_m(\epsilon) = \frac{1}{(m-1)!} \int_0^{\infty} dx \frac{x^{m-1}}{Z^{-1} e^{\beta \epsilon} - \eta}$$

So, now we have this expression for N which is essentially $g V$ over λT of 3 half plus Z , the plus denoting that we are looking at a bosonic system $N_0 Z$. So, as usual the fugacity has to be determined from this relation, but if we look at this as this function f of m η of Z was 1 over m minus 1 factorial 0 to infinity $d x$ x to the power m minus 1 Z inverse e to the power β minus η .

(Refer Slide Time: 01:07)

$$\begin{aligned}
 & \frac{gV}{\lambda_T} \frac{1}{\beta^{3/2}} \frac{2\pi}{\beta^{3/2}} \frac{2}{\beta} \frac{2}{\beta} \sqrt{\pi} \frac{1}{\beta^{3/2}} = gV \left(\frac{2\pi}{\beta^4} \right)^{3/2} \\
 & = \frac{gV}{\lambda_T} \int_0^\infty dx \frac{x^{3/2}}{z^{-1}e^x - 1} - g \ln(1-z) \\
 & \quad \downarrow \\
 & \quad f_{5/2}^+(z) \\
 & \boxed{\ln Q_f = \frac{gV}{\lambda_T} f_{5/2}^+(z) - g \ln(1-z)}
 \end{aligned}$$

$$\frac{1}{m!} \frac{d^m}{dz^m} \int_0^\infty dx \frac{x^{m-1}}{z^{-1}e^x - 1}$$

$m=3/2$

(Refer Slide Time: 01:17)

$$N = \frac{gV}{\lambda^3} f_{3/2}^+(z) + \frac{g}{1-z}$$

$$N = \frac{gV}{\lambda^3} f_{3/2}^+(z) + N_0(z)$$

High Temperature Expansion $\rightarrow f_m^+(z) = \sum_{k=1}^{\infty} \frac{z^k}{k^m} \quad 0 < z \leq 1$

$z=1 \quad f_m^+(z=1) = \sum_{k=1}^{\infty} \frac{1}{k^m} = \zeta(m) \rightarrow$ Riemann Zeta Function

$$f_m^+(z) = \frac{1}{(m-1)!} \int_0^{\infty} dx \frac{x^{m-1}}{e^x/z - 1}$$

I think we did make an error while we sorry this has to be minus of eta for a specific eta. If it was plus then I know that this is just going to be f m plus offset is just going to be minus of 1 beta epsilon. Terribly sorry for the mistake, this has to be e to the power x minus 1.

Now, this is a very complicated function and usually the it is representation in terms of simple functions are not possible, but we do know the high temperature expansion of this ah. The high temperature expansion of f m; so, now, high temperature expansion gives us f m plus of Z was 1 over m minus 1 factorial this was already taken care of.

It was simply sum over k equal to 1 to infinity Z to the power k k to the power m for Z greater than equal to 0 less than equal to 1. One should note that if I set Z equal to 1, so, f m plus of Z

equal to 1 becomes sum over k equal to 1 to infinity 1 over k to the power m and this is zeta of m when the zeta function is the Riemann zeta function.

(Refer Slide Time: 03:17)

Series converges for $m > 1$ and $\zeta_m^+(z) \rightarrow \infty$ for $m \leq 1$ as $z \rightarrow 1$

$\zeta_m^+(z)$ is finite for all $m > 1$ and for $0 \leq z \leq 1$

$$N = \underbrace{gV \frac{\zeta_m^+(z)}{\lambda_T}}_{N_E} + \underbrace{g \frac{z}{1-z}}_{N_0} \quad 0 \leq z \leq 1$$

$$N_E^{\max} = \frac{gV}{\lambda_T} \zeta(3/2)$$

$\zeta(3/2) \approx 2.612$

The series converges for m greater than 1 and f plus m of Z tends to infinity, for m less than 1 as Z tends to 1. So, series converges for m greater than 1 and f plus m goes to infinity, if m is less than equal to 1 as Z tends to 1. On the other hand, f plus m of Z is finite for all m greater than 1 and for Z greater than equal to 0 less than equal to 1. So, coming back to this then I have coming back to this expression for the particle number is f of 3 half plus of Z plus g Z 1 minus Z.

The first term that you see over here is the term is the number of particles which is contained in the excited states and this is the number of particles which are contained in the ground state

N equal to 0. So, this is the term, the first term is the term which is contained which essentially represents the particles contained in the states other than the ground state.

But now, we have clearly seen that this term is limited by this function right and for a Bose gas I know that the maximum value of Z can happen. There is a limit on values of Z that is Z can be greater than equal to 0 or must be less than equal to 1. So, clearly when Z approaches 1, then this part the first term we will write down this as N epsilon maximum there is a maximum number of particles which you can accommodate in these excited states.

And that number is given by, $g V$ over $\lambda^3 T$ zeta 3 half, where zeta 3 half is approximately 2.612. Now, this is a very important inference. You see from the expression for the total number of particles in your system that you can accommodate only a certain number of particles in the excited states. There is a limit upper bound on that.

So, if you keep on adding particles to the system you are going to hit this limit and then if you keep on adding more and more particles where do they go? They go to the ground state and that is when your condensation starts to appear. Sorry not the condensation starts to happen and the condensate starts to appear.

(Refer Slide Time: 07:01)

$$N = \underbrace{\frac{qV}{\lambda_T} \zeta_{3/2}^+ (z)}_{N_E} + \underbrace{\frac{qV}{\lambda_T} \frac{z}{1-z}}_{N_0} \quad 0 \leq z \leq 1$$
$$\boxed{N_E^{\max} = \frac{qV}{\lambda_T} \zeta(3/2)} \sim V T^{3/2}$$

$\zeta(3/2) \approx 2.612$

On the o1

(Refer Slide Time: 07:18)

$$\begin{aligned} &N_G && N_0 \\ &\rightarrow N_G^{\max} = \frac{gV}{\lambda_T^3} \zeta(3/2) \sim V T^{3/2} && \zeta(3/2) \approx 2.612. \\ &N_0 \text{ can be ignored if } z \ll 1 && \textcircled{N} \approx N_0 \\ &\text{On the other hand } \rightarrow N \approx N_0 = \frac{gV}{\lambda_T^3} \frac{z}{1-z} \Rightarrow z = \frac{N}{N+g} \approx 1 \\ &N = N_G + N_0 && 1 = \frac{N_G}{N} + \frac{N_0}{N} \\ &\text{If } z = 1 && N_G = N_G^{\max} && N_0 = N - N_G^{\max}. \end{aligned}$$

This goes as $V T$ to the power 3 half. On the other hand not well let us. So, the second term, this is the term N_0 can be ignored if Z is very very less than 1. So, if you are not hitting the limit of Z to 1. On the other hand, if N the total particle number is dominated by the number of particles in the ground state. So, that you have N_0 is approximately this, you see what happens to Z .

This implies that Z is approximately N over N plus not approximately, but exactly N by N plus g , g is a tiny number compared to N which is 10 to the power 23 typically and therefore, you see this value is 1. So, whenever this condition is satisfied that you actually see that the number of particles in the ground states start dominating the total number of particles in the system, so most of the particles have gone into the ground state then you have actually hit the limit Z equal to 1.

So, in the thermodynamic limit, we rewrite this equation which we had over here and a little up. So, we had the expression N was equal to $N \epsilon$ plus N_0 . We rewrite this equation as 1 is equal to $N \epsilon$ over N plus N_0 over N . Clearly, if N_0 is not sufficiently large, so that you have not hit the $Z \rightarrow 1$ limit, then in the thermodynamic limit you can ignore this term and most of the particles are accommodated in the excited states.

In contrast whenever you have populated all the excited levels there is a limit this ϵ_{\max} you have reached you start populating the ground state and that is when; if your Z is equal to 1 and $N \epsilon$ is equal to $N \epsilon_{\max}$ then you have populated all your excited energy levels and then essentially N_0 is given by you have hit the limit of Z to one as Z is equal to 1. So, you see the N_0 diverges. So, essentially the number of particles in the ground state is given by total number of particles minus $N \epsilon_{\max}$ right.

(Refer Slide Time: 10:19)

$$1 = \frac{N_\epsilon}{N} \quad \text{for } Z < 1$$

$$1 = \frac{N_\epsilon^{\max}}{N} + \frac{N_0}{N} \quad \text{for } Z = 1$$

$$N < N_\epsilon^{\max} = \frac{gV}{\lambda_T} S(3/2) \quad \text{or} \quad N \lambda_T < gV S(3/2)$$

$$N = \frac{gV}{\lambda_T} I_{3/2}^+(z) \quad \text{And the fugacity must be determined from this expression:}$$

So, we conclude therefore, that N over N is equal to 1 for Z less than 1 and 1 is equal to N over N plus N_0 over N for Z is equal to 1. Therefore, we can see that when the total particle number is less than N max, which is gV over $\lambda^3 T$ times $\zeta(3/2)$.

Or we can rewrite this condition as $N \lambda^3 T$ over gV is less than $\zeta(3/2)$ that means you can still accommodate the particles in the excited levels. So, that you have this expression for N . And the fugacity must be determined from this expression as we have done it for a fermion system or an ideal fermi gas.

(Refer Slide Time: 12:22)

$$N = \frac{gV}{\lambda^3 T} F_{3/2}^+(z)$$

And the fugacity must be determined from this expression.

$$N > N_E^{\max} = \frac{gV}{\lambda^3 T} \zeta(3/2) \quad \text{or} \quad \frac{N \lambda^3 T}{gV} > \zeta(3/2)$$

$$N_0 = N - N_E^{\max} = N - \frac{gV}{\lambda^3 T} \zeta(3/2)$$

$$N = \frac{gV}{\lambda^3 T} \zeta(3/2) \rightarrow \text{the condition when condensate starts to appear.}$$

Now, in contrast when N is greater than N epsilon max which is gV over $\lambda^3 T$ $\zeta(3/2)$ or $N \lambda^3 T$ over gV is greater than $\zeta(3/2)$ then you have hit the limit in

putting particles in the excited states. Therefore, in that case your N_0 is given by $N - N_{\text{max}}$ which is $N - \frac{gV}{\lambda^3 T^3}$.

This means that there is a condition at which point the condensate can appear. I can figure out a temperature. So, I can clearly see that based on this the condensate starts to appear when N is $\frac{gV}{\lambda^3 T^3}$. That means, when your number of particles in the system has hit the upper bound upper limit of N of the number of particles you can put in excited levels.

The condition when condensate starts to appear. Again at this point I would like to iterate that look even though we are talking about the condensation and whenever one talks about the condensation one talks about visualize the condensation in a real space, it is not really a condensation in real space. It is actually a condensation in a momentum space, all particles.

So, whatever we have been talking about is labeled by this momentum vector k , the single particle levels are leveled by the momentum vector k . So, what is actually happening is you are actually populating the state with the zero momentum. So, it is a if you can visualize the momentum space then you are going to see a peak which is starting to appear in the zero momentum state and that is exactly what people have seen in experiments.

So, this effectively also means, this essentially means, that for large enough temperatures you have sufficiently large amount of thermal energy to excite the particles in the excited states. So, that they are in the excited states. But as you keep on decreasing the temperature as the temperature comes down sorry, the density becomes high or either you could have the temperature coming down becomes smaller and smaller.

Or the density is raised which means you keep on adding particles and particles until you hit this criteria. What essentially happens is the positive correlation between the bosons ensures that they go and on because they are attractive. So, they go and sit at the ground state energy $\epsilon = 0$.

(Refer Slide Time: 15:52)

So, defining x equal to $N \lambda T$ over $g V$, then the fugacity is defined by Z is equal to 1 if x is greater than ζ of 3 half and solution of x is equal to f plus 3 half Z . So, fugacity, something is wrong here. Fugacity is equal to 1 if x is greater than ζ 3 half and or is the solution of this when x is less than ζ to the power 3 half.

Recall the first leading order correction to this function f 3 half of Z . f 3 half goes as Z for small enough Z . So, that you have the solution x equal to Z . If you want to plot the fugacity, so, this hits a value 1 whenever your x is greater than ζ 3 half, but for small enough you will have Z is equal to x ok not really so, the not drawn to schematics. So, let us just quickly draw it first. For small enough I am going to have and you expect that the curve becomes something like this way.

So, let us shift it a little bit to the right, so that we can say that this is going to be your zeta 3 half and not this. So, this is how your curve should look.

(Refer Slide Time: 18:36)

The Condition for Condensation to appear is given by

$$n = \zeta(3/2)$$

$$\frac{N \lambda_T}{gV} = \zeta(3/2)$$

$$\frac{N}{gV} \frac{1}{\zeta(3/2)} = \left(\frac{2m\pi}{\beta h^2} \right)^{3/2}$$

$$\frac{1}{2m\pi} \left(\frac{n}{g \zeta(3/2)} \right)^{2/3} = k_B T c$$

$$\lambda_T = \left(\frac{\beta h^2}{2m\pi} \right)^{1/2}$$

$$\lambda_T = \left(\frac{h^2}{2m\pi} \right)^{1/2}$$

The condition for condensation to appear is given by n equal to zeta 3 half right which is $N \lambda_T$ over gV is going to be zeta of 3 half. So, now, λ_T is βh^2 over $2m\pi$ raised to the power half. So, that the thermal de Broglie volume is βh^2 over $2m\pi$ raised to the power 3 half. So, then N over gV 1 over zeta 3 half is equal to 1 by βh^2 square twice $m\pi$ raised to the power 3 half.

So, capital N by V is a small n the number density g zeta 3 half raised to the power two-third. I have 1 over twice $m\pi$ which is going to be your $k_B T c$. So, we will replace the β here by βc indicating that this gives me the temperature.

(Refer Slide Time: 20:25)

$$\frac{N \lambda_T}{gV} = \zeta(3/2)$$

$$\frac{N \lambda_{T_c}}{gV} = \zeta(3/2) \quad \left(\frac{2m\pi}{h^2} \right)$$

$$\lambda_{T_c} = \frac{gV \zeta(3/2)}{N} \quad \lambda_T = \left(\frac{h^2}{2m\pi} \right)^{3/2}$$

$$\frac{N}{gV} \frac{1}{\zeta(3/2)} = \left(\frac{2m\pi}{\beta h^2} \right)^{3/2}$$

$$\frac{h^2}{2m\pi} \left(\frac{n}{g \zeta(3/2)} \right)^{2/3} = k_B T_c$$

$$k_B T_c = \frac{h^2}{2m\pi} \left[\frac{n}{g \zeta(3/2)} \right]^{2/3}$$

$$N_\epsilon = \frac{gV \zeta(3/2)}{h^2}$$

$$N_\epsilon \sim T^{-3/2}$$

$$\frac{N_\epsilon}{N} = \frac{gV \zeta(3/2)}{\lambda_T N} = \frac{\lambda_{T_c}}{\lambda_T}$$

$$\frac{N_\epsilon}{N} = 1 \quad \text{for } T > T_c$$

So, you have a critical temperature $k_B T_c$ which is given by $\frac{1}{2m\pi} \frac{n}{g \zeta(3/2)}$ raised to the power $2/3$. I am missing out a factor of h^2 . So, that this has to be h^2 in the denominator. So, this is the critical temperature that you are looking at. At this temperature your condensation starts to happen and you start to see a condenser that appears at the k equal to 0 momentum state.

Now, the particle number in the excited state N_ϵ / N is equal to 1 for $T > T_c$ because all the particles that you put in essentially go into the excited states if you are away from this critical temperature, but the moment you hit the critical temperature you essentially hit a limit of $gV / \lambda_T \zeta(3/2)$. So, that this N_ϵ goes as T to the power $V T$ to the power $3/2$.

And you clearly see that from this condition that we had that this gives me the temperature at which the condensate starts to appear. So, I can sort of write down this as $\lambda T c g V$ is equal to $\zeta 3/2$. So, that $\lambda T c$ is equal to $g V$ over $N \zeta 3/2$ right. Or essentially I can write down $g V$ over N and if I look over here then $g V$ over ζ times $\zeta 3/2$ divided by N which is $N \epsilon$ over N is $g V \lambda T N \zeta 3/2$ which is essentially $\lambda T c$ over λT .

(Refer Slide Time: 23:10)

$$\begin{aligned}
 & \left[\frac{2m\pi}{h^2} \int_0^\infty \zeta^{3/2} \right] & \frac{N \epsilon}{N} &= \frac{g V}{4\pi N} \zeta^{3/2} = \frac{\lambda T c}{\lambda T} \\
 & & &= \left(\frac{T}{T_c} \right)^{3/2} \\
 \frac{N \epsilon}{N} &= 1 & \text{for } T > T_c \\
 &= \left(\frac{T}{T_c} \right)^{3/2} & \text{for } T < T_c \\
 \frac{N_0}{N} &= 0 & \text{for } T > T_c \\
 &= 1 - \left(\frac{T}{T_c} \right)^{3/2} & \text{for } T < T_c \\
 & & \left[\begin{aligned} 1 &= \frac{N \epsilon}{N} + \frac{N_0}{N} \\ \frac{N_0}{N} &= 1 - \frac{N \epsilon}{N} \end{aligned} \right]
 \end{aligned}$$

So, this is therefore, T over T_c raised to the power 3 half. So, this is T over T_c raised to the power 3 half for T less than T_c . So, as you start hitting the critical temperature you get a you start to get this. Now, the number of particles in the ground state is 0 for T greater than T_c .

However, as you cross the critical temperature then this becomes one minus T over T_c raised to the power 3 by 2 and this expression follows from the fact that 1 plus 1 is equal to N

epsilon by N plus N 0 over n. So, that N 0 over N is 1 minus N epsilon over N. If you carefully study these two expressions one can plot them all. So, you see that as you approach 0 and 0 temperature the number of this thing vanishes.

(Refer Slide Time: 24:28)

So, that I have this is my T_c let us say; we will draw a vertical line and let us say this is one then this is going to be $N \epsilon$ over N number of particles in the excited states for T greater than T_c and this goes as $(T/T_c)^{3/2}$. For temperatures higher than T_c the occupation in the ground state energy level is 0.

And as you start going below the critical temperature the occupation in ground state starts to increase going as T to the power $3/2$. So, that sorry, $1 - (T/T_c)^{3/2}$ and so that you have the plot which looks something like this. So, that this is $1 - (T/T_c)^{3/2}$.
