

Introduction to Quantum Field Theory (Theory of Scalar Fields) - Part 2
Prof. Anurag Tripathi
Department of Physics
Indian Institute of Technology-Hyderabad

Lecture - 29
Renormalization -Part 1

Okay. So let us begin the process of getting finite answers in quantum field theory for various observables and as I had mentioned earlier this procedure is called renormalization, okay? So let me briefly summarize what we have done so far.

(Refer Slide Time: 00:38)

Renormalization.

Summary: Integrals diverge
 Dimensional reg.: At one loop: en 4d - simple pole in ϵ
 $d = 4 - 2\epsilon$

$$S = \int d^d x \left(\frac{1}{2} \partial_\mu \phi \partial^\mu \phi - \frac{1}{2} m^2 \phi^2 - \frac{\lambda}{4!} \phi^4 \right)$$

Instead of working with this action, we work with

$$S = \int d^d x \left(\frac{1}{2} \partial_\mu \phi \partial^\mu \phi - \frac{1}{2} (m')^2 \phi^2 - \frac{\lambda'}{4!} \phi^4 \right)$$

$[S] = [\hbar]$
in Natural units $\hbar = 1$
 $c = 1$

$[q_\mu] = 1$
 $[d^d x] = -d$

$d x^0 d x^1 d x^2 \dots d x^{d-1}$

$[S] = 0$

$-d + 2 + 2[\phi] = 0$
 $[\phi] = \frac{d-2}{2} = 2-\epsilon-1 = 1-\epsilon$

So we have seen that the integrals diverge the moment you go to one loop okay and we have also seen using dimensional regularization how exactly these divergences appear, this ultraviolet divergences appear in the theory, okay? And we have seen that we get simple poles at one loop in 4 dimensions. As you approach 4 dimensions, you get simple poles in epsilon, okay where you take d equal to 4 minus 2 epsilon and let epsilon goes to 0.

So now our next step is to build the dimensional continuation, which we did for the integrals directly into the Feynman rules okay that is what we want to do now. But none of this is going to solve any of our problems as such, but what it will do is it will make it easier to or more systematic to understand the similarities, okay, what kind of similarities will appear in a more systematic manner rather than just looking at the individual Feynman diagrams, okay.

So that is what I want to do. And as I said, this is not going to make anything finite because I have to take epsilon going to 0 eventually, meaning I should work in 4 dimensions and all those integrals will diverge, okay. But nevertheless, this will be the first step towards our goal of getting final answers, okay? So let us begin with that.

So again, my all the work that I will do will be in the phi four theory, whose action is this $\int d^4x \frac{1}{2} \partial_\mu \phi \partial^\mu \phi - \frac{1}{2} m^2 \phi^2 - \frac{\lambda}{4!} \phi^4$, okay? But now I want to use a different action, not this one, which will be given by this. So instead of working with this section we work with the following.

So I will work instead with integral $\int d^d x$ okay, I am going to d number of space time dimensions, okay? And you have again $\frac{1}{2} \partial_\mu \phi \partial^\mu \phi$ that will not change because after all this is what this is $\int d^d x \left(\frac{1}{2} \phi^2 + \frac{1}{2} \phi^2 + \frac{1}{2} \phi^2 + \dots \right)$ and so forth. And if you have d number of them let us say d is integer then it is just a more number of terms, right?

So it will have $\int d^d x \left(\frac{1}{2} \phi^2 + \frac{1}{2} \phi^2 + \frac{1}{2} \phi^2 + \dots + \frac{1}{2} \phi^2 \right)$ and so forth up to $\int d^d x \phi^2$, okay? But I am going to view it not as a d as an integer but I will let it even take fractional values okay. But we will not worry so much about what exactly it means to have d as fractional okay and worry about those details. Our aim will be just to get Feynman rules which are valid and eventually which give integrals which are of this form.

(Refer Slide Time: 04:52)

Another integral that is divergent at one loop in 4 dimensions is

$$I = \int \frac{d^4 k}{(2\pi)^4} \frac{1}{(k^2 - \Delta + i\epsilon)}$$

; one propagator

$$\Gamma\left(N - \frac{d}{2}\right) : N = 1, d = 4 - 2\epsilon$$

$$\Gamma(-1 + \epsilon)$$

$$z\Gamma(z) = \Gamma(z+1)$$

$$(-1 + \epsilon)\Gamma(-1 + \epsilon) = \Gamma(\epsilon)$$

$$\Gamma(-1 + \epsilon) = \frac{1}{-1 + \epsilon} \cdot \Gamma(\epsilon) = \frac{1}{-1 + \epsilon} \left(\frac{1}{\epsilon} - \gamma_E + \mathcal{O}(\epsilon) \right)$$

→ Singularity appears as a simple pole.

So instead of getting integrals of this form, I will start getting integrals directly of these forms, like these ones, okay.

(Refer Slide Time: 05:06)

So, the result in Minkowski space is

$$\int \frac{d^d k}{(2\pi)^d} \frac{1}{(k^2 - \Delta + i\epsilon)^N} = \frac{i (-1)^N}{(4\pi)^{d/2}} \frac{\Gamma(N - \frac{d}{2})}{\Gamma(N)} \left(\frac{1}{\Delta - i\epsilon} \right)^{N - \frac{d}{2}}$$

$$\int \frac{d^d k}{(2\pi)^d} \frac{1}{(k^2 + 2p \cdot k - \Delta + i\epsilon)^N} = \int \frac{d^d l}{(2\pi)^d} \frac{1}{[l^2 - (p^2 + \Delta) + i\epsilon]^N}$$

$$\int \frac{d^d k}{(2\pi)^d} \frac{1}{(k^2 + 2p \cdot k - \Delta + i\epsilon)^N} = \frac{i (-1)^N}{(4\pi)^{d/2}} \frac{\Gamma(N - \frac{d}{2})}{\Gamma(N)} \left(\frac{1}{p^2 + \Delta - i\epsilon} \right)^{N - \frac{d}{2}}$$

Here, which are already continued. So that is all we are trying right now. Okay, I am not trying to worry about what it means to have an action in fraction number of dimensions, okay or even yeah. So let me write it as minus half, instead of m, I will write m prime. So m prime square phi square minus lambda over 4 factorial, lambda prime over 4 factorial phi to the four, okay?

I have just renamed m to m prime and lambda to lambda prime, okay? Okay, so I want to work with this integral. And now this is in, instead of 4 dimensions it is in d dimensions. So let us do the first simplest exercise of checking the mass dimensions

of the fields and these mass parameter and the coupling constant that appear here, okay? And remember to do that, we should remember that S has dimensions of \hbar , alright Planck's constant, okay?

They have the same dimension. If you check, look at action okay, and convince yourself that action has mass dimensions of this constant \hbar if you have not already done so. Then because we are in natural units in which \hbar is 1, also c is 1, it means that because \hbar is 1 a number, it is a dimensionless object okay, in these units, then action is dimensionless, meaning the mass dimension of S is 0 okay, it is m^0 , okay?

So now let us determine the mass dimension of m' and λ' and ϕ . Now I cannot start that exercise from this term or this term, okay, because here there are two objects whose mass dimensions are not determined ϕ , I do not know what is the mass dimension of that okay, because now I am in d dimension.

The mass dimension of ϕ , what it used to be in 4 dimension is not going to be true. And also in this term, I have another factor m'^2 . So I cannot disentangle from here the mass dimension of ϕ and mass dimension of m' separating, okay? So I should go to a term in which I do not have this issue and which is this one, first term, okay?

There is only field ϕ for which I need to figure out the mass dimension because the dimension of ∂_μ is known. ∂_μ is just a derivative with respect to a particular coordinate so that its dimension will be 1. So this I know, okay? ∂_μ , the mass dimension of that will be $-d$ right, because you have $\partial_0, \partial_1, \partial_2$ so and so forth ∂_x and sorry $d - 1$. So they are each of them has a mass dimension of -1 .

So the total mass dimension will be $-d$, okay? So this has $-d$, ∂_μ has 1. So $-d$ plus for this it is 1, four that it is 1 so 2 plus must dimension of ϕ , but there are two such factors. So two times of it. And that all should add up to 0 because action is dimensionless. So each term should be dimensionless. So what does that give? That gives d is equal to sorry mass dimension of ϕ is equal to $d - 2$.

That is what in general case. But for us, because we are taking d equal to $4 - 2\epsilon$, okay. So 4 over 2 is 2 minus yeah, correct. So 4 over 2 is 2 minus ϵ , and then you have -1 coming from here -1 . So this is 1 minus ϵ , okay? So that is the mass dimension of ϕ . Let us now find out the mass dimension of m . So again the same exercise.

(Refer Slide Time: 10:05)

$$\begin{aligned}
 [m'] &= 1 \\
 d^d x \cdot (m')^2 \cdot \phi^2 & \\
 \downarrow & \quad \quad \quad \downarrow \\
 -d + 2[m'] + \frac{d-2}{2} &= 0 \\
 \Rightarrow [m'] &= 1 \\
 \\
 -d + [\lambda'] + 4 \frac{[d-2]}{2} &= 0 \\
 [\lambda'] + d - 4 &= 0 \\
 [\lambda'] = 4 - d &= 4 - (4 - 2\epsilon) \\
 &= 2\epsilon
 \end{aligned}$$

$$\begin{aligned}
 \text{on } d = 4 - 2\epsilon \\
 [\phi] &= 1 - \epsilon \\
 [m'] &= 1 \\
 [\lambda'] &= 2\epsilon \\
 \text{Redefine} \\
 \lambda' &= \mu^{2\epsilon} \lambda \\
 \mu &\rightarrow \text{some arbitrary mass scale} \\
 \lambda &\rightarrow \text{dimensionless} \\
 m' &= m
 \end{aligned}$$

M prime sorry, this you will find that this is 1 . Let us check how. So mass dimension of ϕ , so ϕ square is here. So it will be d minus 2 over 2 okay and sorry d minus 2 because two factors, okay. So d minus 2 over 2 is for each ϕ . So two times of it, so it is $d - 2$. And you have a $-d$. Okay, so let us write down there. d dx you have and then you have m prime square and then you have ϕ square okay?

So this is giving you $d - 2$. That gives you $-d$ and this is 2 times of m prime. And that should add up to 0 . And you see that m prime has dimensions of mass so it is 1 , okay? From this m prime is 1 , mass dimension of m prime is 1 , okay? And let us now look at λ prime. Remember λ prime or equivalently λ in 4 dimension it used to be dimensionless, okay?

Let us see what happens when you go to d dimensions whether λ prime is still dimensionless, okay? So again d dx so it gives you $-d$ plus λ prime, dimension of λ prime plus ϕ to the 4 , so 4 times $d - 2$ over 2 okay because each of ϕ has dimension $d - 2$ over 2 from here, okay. So what does that give? This gives λ prime 4 d over 2 is $2d$. $2d - d$ is d .

And this is -4 or λ' is equal to $4 - d$ minus, okay? So as you see this is correct because if d is 4 then you get $4 - 4$ zero. So λ' becomes dimensionless in 4 dimension which is something you already knew, okay? And this $n = 4 - 2\epsilon$ dimensions becomes 2ϵ , okay? So λ' has dimensions 2ϵ . Let me record all this here.

Φ has dimension $1 - \epsilon$, m' has dimension 1 . That did not change from 4 dimension, it is still the same. λ' has dimension 2ϵ , okay? So what I will do now is I will redefine. I will just a second. I will redefine this λ' such that in this way. λ' I will call it μ to the 2ϵ times λ because that is how I want to write λ' .

So this is basically defining λ . μ is some arbitrary mass scale, Okay? So what is the benefit? By doing this λ becomes dimensionless right, because if you look at the mass dimension of λ' this says mass to the power 2ϵ . So when you take it on the right hand side the mass dimension of this, mass dimension of μ will be, μ to the 2ϵ will be 2ϵ .

And because now the mass dimension of left hand side is already taken care of by the factor μ to the 2ϵ , λ is dimensionless, okay? And also note that μ is completely arbitrary. This has no relation with any of the physical scales in any problem okay, which you are doing. Because here the purpose of μ is just to absorb the mass dimension of λ' okay, so that I can have λ to be dimensionless.

Also I will instead was calling m' I will call it m , okay? The reason I put m' in the beginning because I wanted to check what is the mass dimension and if it also had some, it has changed its mass dimension then I would have similarly introduced some scale okay, mass scale. But because it turned out to be again having the same mass dimension as before I am not changing it, okay.

So that is the notation I want to use now. So I will write that action using these λ and m .

(Refer Slide Time: 15:48)

$$S = \int d^4x \left[\frac{1}{2} \partial_\mu \phi \partial^\mu \phi - \frac{1}{2} m^2 \phi^2 - \lambda \frac{\phi^4}{4!} \right]$$

$[m] = 1 ; [\lambda] = 0$ $\int \phi = \phi'$

Let us define

$$\phi = z_\phi^{1/2} \phi_R$$

Multiplicative renormalization \leftrightarrow

$$m = z_m m_R$$

$$\lambda = z_\lambda \lambda_R$$

$z_i = 1 + z'_i$
 $i = \phi, m, \lambda$
 z'_i starts at order λ
 z'_i starts at order λ^2

$z_\phi, z_m, z_\lambda \rightarrow$ renormalization constants

$$z_i(\lambda, m) = z_i(\lambda_R, m_R)$$

$\phi_R, m_R, \lambda_R \rightarrow$ renormalised fields & parameter λ_R

So my action becomes integral d dx half del mu phi delta mu phi minus half m square phi square minus mu to the 2 epsilon lambda over 4 factorial phi to the 4, okay? That is the action with which I want to work, okay? And remember lambda is dimensionless now, okay. So I will just write this here, okay.

Now some time back in I think in the previous course probably I had told you that we can change the, we can redesign the fields, okay? There is nothing secret about half delta mu phi del mu phi. Even the factor half here, this factor half, you could absorb into phi.

You could say I do not want to work with this phi, but I will work, I will define half phi to be let us say phi prime and I will write this action as del mu phi prime del mu phi prime and this half vector will start appearing in these pieces, okay? That is something you could do and we also had introduced some factor of z and redefined. So what I am going to do now is I am going to redefine the fields and these parameters again, okay?

And you will see later why that will be useful. But for now I will do this, okay? So let us define phi to be z phi to the half okay times phi R. And m to be z m times m R and lambda to be z lambda times lambda R okay? Where phi R m R and lambda R are the fields which are finite and these z's they are so z i where i is phi and m 1 lambda is of

this form $1 + z_i$ let us call it z_i prime okay, where z_i prime starts at order λ , okay?

So I am saying that instead of working with ϕ , I want to work with ϕ_R , okay. And here is some change in the normalization of the field. Okay, I am just changing the normalizations of the field and of these m 's and λ 's. And I have introduced these factors, okay. And I say that these factors are of this form $1 + z_i$ prime, okay? Like z_m is $1 + z_m$ prime.

And where the property z_m prime has is that it starts at order λ , okay? It does not have a order one term, it starts at order λ , okay? It will be λ times something plus λ^2 times something and so forth, okay? So that is the redefinition I do. And these constants z_ϕ , z_m and z_λ , sorry, these are called renormalization constants, okay.

And these z 's are functions of λ and m okay, and because λ is a function of λ_R okay, m is a function of λ because there is a factor of z_m ; z_m depends on λ and m , but λ is a function of λ_R , m is a function of m_R . So all these z 's are basically functions of λ_R and m_R right, because of these relations, okay? An important point is that z_i is $1 + \text{order } \lambda_R$ terms, okay?

So here I said z_i prime starts at order λ but now because λ itself starts at order λ_R okay because λ_R times z_λ and z_λ is $1 + \text{something}$. So this statement then becomes z_i prime starts at order λ_R okay because of this, this relation. So all these renormalization constants are actually functions of λ_R and m_R , the way I have defined all this.

So also another thing I should tell you that this, the way I have redefined these fields, you will see soon the nature of the z 's that they are going to absorb infinities, okay? And we will see what all this means after we have done the calculation, okay? It is easier to appreciate once the calculation has been done when you have seen everything explicitly.

Then one understands why this has worked or what is the meaning of doing all this, okay? Beforehand it is a bit difficult to appreciate. So yeah, one thing I wanted to say here is that this is called multiplicative renormalization okay, when you have this renormalization constants multiplying the renormalized fields, okay? When I am using subscript R okay to a field or a parameter, I call it as a renormalized field.

So ϕ_R , m_R and λ_R these are renormalized fields and parameters, whether it is a mass parameter or a coupling constant, okay? And this because this is multiplicative, the z factors are multiplying the ϕ_R 's, this is called multiplicative renormalization. Okay, I should have used some color. Okay, so this is multiplicatively renormalization. These are the renormalization constants.

And these fields and mass parameters these are called renormalized fields and the renormalized mass parameter and renormalized coupling constant, okay? So good I have said a lot of things here but mostly it is just redefining something, okay? Now whether all this will be useful or not we have to see later. But no one can stop me from doing what I have done just now, okay.

There is no way you can stop me from saying that this is not allowed. You cannot say that I cannot write ϕ as $z \phi_R$ because this is allowed. I can redefine the field. Similarly mass parameter I can write it as a product of these two okay where $z m$ is some constant okay, and $z \lambda$ is some constant. I can write it this way, okay.

So you cannot stop, not because you are not physically present here to stop me but because there is nothing inconsistent that I am doing. So I am allowed to do this. Okay, so let me put this back into the action and see how the action looks like, okay? But it is still the same action okay, this action. I am not going to change anything. It is the same action I rewrite differently.

(Refer Slide Time: 25:06)

The same action (the same theory) now looks like

$$S = \int d^d x \left[\frac{1}{2} z_\varphi \partial_\mu \phi_R \partial^\mu \phi_R - \frac{1}{2} z_\varphi z_m^2 m_R^2 \phi_R^2 - \frac{1}{4!} \lambda^{2\epsilon} z_\lambda z_\varphi^2 \lambda_R \phi_R^4 \right]$$

Add & subtract $\frac{1}{2} \partial_\mu \phi_R \partial^\mu \phi_R - \frac{1}{2} m_R^2 \phi_R^2 - \lambda^{2\epsilon} \frac{\lambda_R \phi_R^4}{4!} m_R$

$$S = \int d^d x \left[\frac{1}{2} \partial_\mu \phi_R \partial^\mu \phi_R - \frac{1}{2} m_R^2 \phi_R^2 - \lambda^{2\epsilon} \frac{\lambda_R \phi_R^4}{4!} + \frac{1}{2} (z_\varphi - 1) \partial_\mu \phi_R \partial^\mu \phi_R - \frac{1}{2} (z_\varphi z_m^2 - 1) m_R^2 \phi_R^2 - \lambda^{2\epsilon} \frac{\lambda_R}{4!} (z_\lambda z_\varphi^2 - 1) \phi_R^4 \right]$$

So S the action becomes the same action, the same theory, now looks like the following. Half z_φ phi to the half times phi R , $\partial_\mu \phi_R$ okay, again there is a $\partial_\mu \phi_R$ and that also brings a factor root z , square root of z and those two square roots of z make z phi, okay. So that is first term. Then you have the mass term and that becomes minus half. We had m square so and also phi R square, sorry phi square.

So phi R , phi when I write in terms of phi R , it becomes phi R square and it will bring a factor of z phi, okay? So that is what I am writing here. Then you have m square and when you write it in terms of $m R$ square, it will bring a factor of $z m$ square, okay because $z m$ times $m R$ is what is m . So the square of it gives you $z m$ square $m R$ square, okay.

Then you have minus 1 over 4 factorial, let us stop writing now, μ to the 2 epsilon, okay? Then you can check that you get z lambda times z phi square times lambda R times phi R to the 4, okay? Let us check whether this is correct. Because you had phi to the 4 okay, it will bring 4 powers of square root of z phi that means z square.

And then we had lambda here and that brings z lambda and this is μ to the 2 epsilon, which was present and minus 1 over 4 factorial, okay. So that is how the action looks like now for the same theory. The physical content has not been changed, okay? It is all the same. I have just redefined fields. But that does not change the content of the theory.

Meaning, if you were calculating some observable earlier using S and you do it again, you will get the same result. The only thing is that earlier, you are getting nothing because you are getting infinities and now also it is the same. So you still do not get anything sensible but as far as the theory is concerned it is the same theory, okay? So now this does not look like what we are used to.

So I will now add and subtract the following to this section, okay? Add and subtract the same thing so that I do not alter the action. So add and subtract $\frac{1}{2} \partial_\mu \phi \partial_\mu \phi - \frac{1}{2} m^2 \phi^2$, okay. So this is something in terms of the renormalized fields and renormalized mass parameter, okay? So I will just add and subtract this to the Lagrangian density and my action will become the following.

So S is $\int d^4x$. So I am adding now first $\frac{1}{2} \partial_\mu \phi \partial_\mu \phi - \frac{1}{2} m^2 \phi^2$, okay?

Now I should subtract this from this section right, so that it means that I have not done anything, I have not altered anything in the action. So when I do so I will get the following terms. So I will write this $\frac{1}{2} \partial_\mu \phi \partial_\mu \phi$ and subtract from it $\frac{1}{2} \partial_\mu \phi \partial_\mu \phi$, which will give me $\frac{1}{2} \partial_\mu \phi \partial_\mu \phi$, so that is the term which is present.

And from, when I am subtracting this, this gives a -1 , $\partial_\mu \phi \partial_\mu \phi$, the laptop has slowed down suddenly, okay anyway. Okay, let us check whether this is correct. So you have here, if you take this first term and this term and add them up, what do you get?

Because of this -1 this term cancels okay and you are left with only $\frac{1}{2} \partial_\mu \phi \partial_\mu \phi$, which is what you had originally okay, which means that I have not changed the first term as I have written here, okay? Now let us look at minus $\frac{1}{2} m^2 \phi^2$ term that I have added. So I should subtract it and I will subtract it from here.

So minus half, it looks like I cannot write at all, minus half, let me try again. $\frac{1}{2} \partial_\mu \phi \partial_\mu \phi - \frac{1}{2} m^2 \phi^2$, I just want to finish this action, not letting me, $m^2 \phi^2$

square ϕR square, okay. So let us check whether this is fine. Again minus half times minus 1 is half, so half $m R$ square ϕR square okay with the plus sign that cancels against this one, okay?

So that I get rid of and what is left with is, what is left is half $z \phi z m$ square half $z \phi z m$ square with the minus sign $m R$ square ϕR square. So that is also correct. Now let me write down the last term. Minus μ to the 2 epsilon okay? Then you have λR over 4 factorial, and then z of λ , z of ϕ square minus 1.

You can check that this is the right factor and ϕR to the 4. This is difficult, okay. So finally I managed to write this. Okay, so that is how the same action which I wrote earlier in terms of ϕ 's looks like when I write in terms of ϕR , okay? Now let me tell you why I have done this before I proceed further and anyway I cannot proceed further in this video because I am unable to write at all.

So see the way it was written here, in this on the top here. Okay, now it works. Okay this is working now. Okay, so the way it was written here in, the way the action was written on the top had $\partial \mu \phi R \partial \mu \phi R$, that is the usual kinetic term but then you have a $z \phi$. But $z \phi$ is a function of λR and $m R$ which are your constants, okay?

So I do not want to put it this way but I want to put it in the canonical form the way usually we write the kinetic term without coupling constants, okay. And that is why I have written it this way because once I write it this way, the propagator in the theory will be exactly the same which I had earlier, okay. Instead of m I will have $m R$ but other than that everything looks the same.

So that is why I have added and subtracted that term so that I in the action I have the parts, the parts which were present earlier, okay. I think I missed this one. So not only add and subtract this, I also wanted to add this one, this one I forgo, okay. So you see that I have added and subtracted the entire action that we used to have.

The only difference is that instead of ϕ I have ϕR but looks exactly the same, okay? So here also okay, which is good, because when I am writing the Feynman

rules, I will have exactly the same Feynman rules with the only difference being that the names would have changed for the parameters and μ to the 2ϵ will appear in the vertex. But other than that, everything is the same.

And there is another difference that will come here is, you have more terms, so you have more vertices, okay? Let us look at this term okay? This has $z\phi$; $z\phi$ starts with 1. So that 1 cancels 1 and it is left with $z\phi'$, which I had earlier defined okay, which starts at λ or λR . So this term would contain a factor of λ . So that is a coupling term, right?

This is a kinetic term. Here, it does not contain any factors of coupling, but here it does. So that is a coupling term. That is an interaction term, which has derivatives here, but it is still an interaction term. Similarly this one, okay? This is also quadratic like this one this term.

But again, it contains factors of coupling okay, coupling constant λR and that is why this is also an interaction term and the same is true for this one also okay, because they are factors of λ and any way this is not even quadratic, that is quartic. So that is also a coupling term, okay.

So compared to the theory written in terms of ϕ and m and λ , this has more number of vertices in the theory okay, more number of interaction terms in the theory. So now I will give you the Feynman rules and you can immediately see that these are the correct ones. So let us, first let us write down, let us write down the propagator.

Maybe I should, okay let me take it to the next page. Okay, here and then here I will just paste it. I hope that this will be also easily visible, okay.

(Refer Slide Time: 40:10)

$$S = \int d^4x \left[\frac{1}{2} \partial_\mu \phi \partial^\mu \phi - \frac{1}{2} m^2 \phi^2 - \frac{\lambda}{4!} \phi^4 \right] \leftarrow$$

$$+ \frac{1}{2} (m_R)^2 \phi^2 - \frac{1}{2} (z_\phi z_\phi - 1) m^2 \phi^2 \leftarrow$$

$X \sim \mathcal{O}(\lambda_R^2)$ $\xrightarrow{L_2}$  $i \left(\frac{1}{2} (z_\phi - 1) p^2 - \frac{1}{2} (z_\phi z_\phi - 1) m^2 \right)$

 $-i p^{2\epsilon} \frac{\lambda_R}{4!} \cdot \underbrace{(z_\lambda z_\phi^2 - 1)}_{\propto \mathcal{O}(\lambda_R)}$

So that is how the action looks like now, okay. So what are the Feynman rules then? Feynman rules. Or maybe I will, okay now I cannot move it. So Feynman rules. Remember it is still the same theory, I have not changed really anything okay, physical content everything is the same. Redefining certain things cannot change the physics content. So how about the propagator?

Propagator is given by these first two quadratic terms and this is of exactly the same form as before so I also get the same thing as before. But now it will be m_R square. And remember m_R is still a mass parameter, okay? It is not a physical mass of anything, because you remember how we find the physical mass of particles in the theory.

You can look at the poles of Green's functions or let us say 2 point function, okay. And look at the pole and that pole will give you the physical mass. The physical mass will be a function of λ and R , sorry, λ and m which in our case now has become functions of m_R in λR . So physical mass will be a function of m_R and λR , okay.

So m_p would be, m_p 's physical mass will be some function of m_R and λR , okay? That is what we can say but m_R is not itself the physical mass, okay. So that is one of the Feynman rules. Then as before we have this vertex coming from minus λR over 4 factorial ϕ to the R , but you have a factor of μ to the 2 epsilon

also. And remember, recall that the vertex here was minus i lambda over 4 factorial earlier, that is what we had minus i lambda over 4 factorial.

So instead of lambda, I will have lambda R , okay. And I also have factor m mu to the 2 epsilon okay, which is basically i times minus lambda R over 4 factorial mu to the 2 epsilon, okay. So you see that minus lambda R over 4 factorial is this minus lambda R over 4 factorial and this is a factor of phi, okay.

If you go back to the first course you will see how this factor of i came out okay, in the Green's functions because we had written everything in terms of how to say vacuum expectation values of fields and then there was an exponential and e to the i of that interaction term and that is from where the i was coming okay, when you expand the exponential.

So it is that i but now unlike the fact that you had only this term in the expression of Green's function okay, you also have these terms, okay. So which means that these will also give you vertices. So let us look at this, these two terms now. There are two terms in this line, so let us take both of them and $\delta \mu \phi R \delta \mu \phi R$ that will give you a factor of p square, okay?

When you take the derivatives it pulls out factors of $i p$ okay? So you will get the following. So this vertex I am drawing it this way because it has only two fields phi's that appear ϕR and ϕR okay and so it has two external lines. This one also has phi square, so two external lines, okay? And you get R times half z phi minus 1 p square minus half z phi, sorry, $z m$ square minus 1 $m R$ square.

Let me check. Okay, looks fine. $Z m$ square minus 1 $m R$ square, okay? So you see you have in this theory, I mean it is the same theory, but the way we have rewritten things, you also have a vertex which is a two point vertex, okay? We never had such a vertex before, we always had a 4 point or a 3 point vertex, but it is the first time we are seeing a 2 point vertex, and these are usually denoted by putting a cross, okay?

So all those vertices in this action which carry effectors of z okay, or $z m$ or whatever, they will be denoted by this cross, by putting a cross on the vertex. And there is one

more that you have which is a 4 point vertex coming from this last line, okay. And I have put a cross because this also has factors of z 's. And it is a 4 point vertex because you have 4 fields, okay.

So 4 lines you can connect that is why it has 4 legs. So this is e to the sorry i minus R times 2 epsilon λR over 4 factorial times z λz ϕ square minus 1 , okay. So these are our Feynman rules with which we should work. And remember we have a , we always have momentum conservation at each vertex when we are drawing Feynman diagrams and that momentum conservation is now d dimensional, okay?

So it is really 2π to the d and δ^d and the sum of all momenta that are entering into that vertex, okay? So that is the only other thing that you have to keep in mind. Now given that we have these Feynman rules let us first figure out whether these three new vertices or sorry these two new vertices they are of the same order as the 4 point vertex here or are they different. So this one this vertex is of order λ , λR okay.

So this vertex is of order λR , okay. Now let us look at this one. This vertex has z ϕ and this term. Let us look at z ϕ . So z ϕ is 1 plus z prime ϕ okay or whatever 1 plus some function that starts at order λR . So that one cancels and whatever you have here starts at order λR , okay? So this two point function clearly starts at order λR , sorry this 2 point vertex not 2 point function.

So this is also vertex that is of order λR . Now let us look at this 4 point vertex which you have in this way of writing. Here it already has an explicit factor of λR , right because you have a factor of λR here. Then z λ and z ϕ they start at order 1 . So z λz ϕ square, the lowest order term in this will be 1 . So that 1 will cancel this 1 , okay.

And the second term, the next term in these will be of order λ , λR , okay? So you see that this factor contribute something of order λR , okay? That order λR term times this λR makes this vertex order λ square, order λR square, okay? So this is a vertex that is of higher order compared to these two vertices.

So if you are calculating something only up to order λ_R , then you do not need to use this last vertex because that contributes at order λ_R^2 , okay? So one has to be also careful in using this because these are of different orders, okay. Now we have all these Feynman rules and we have modified or redefined the fields in terms of renormalized fields and renormalized mass parameter and renormalized coupling constant, okay.

But nothing has really changed. You still calculate whatever you want, you will get infinity okay, because just redefining things cannot help. So we will see how to get finite answers in the next video.

But here I want to also bring your attention to the fact that even though you have several interaction terms in this section like this ϕ^4 term, and this interaction term which has $\mu \phi^2$ coupling and this ϕ^4 , these coupling constants are not independent, okay? They are not all different, they are not all independent.

They all are completely determined in terms of λ_R and m_R okay. So because you know a long back I was telling that whenever you write a interaction term in the Lagrangian you have to include a coupling constant and these coupling constants are independent of each other in general unless certain symmetries force them to be related, they are independent.

And here you see that it is just because we have rewritten things in certain way that is why these couplings are still known are given by these two coupling constants, λ_R and m_R . The number of coupling constants has not changed. It is the same theory, okay. So all this algebra will be very useful, all these calculations will be very useful now in setting up the procedure to get finite answers okay, and that is what we will take up next.
