## Composite Systems: Pure States, Schmidt Decomposition, Operators Acting on Composite Systems-Part 02

So, we can have a formal treatment of finding out whether a state is an entangled state or not and what is the canonical form of a motion rule state, okay. We call it Schmidt decomposition. So, in this Schmidt decomposition let us take state  $|\psi\rangle$ , which is sum over  $ij$ ,  $\alpha_{ij}$ ,  $|\psi_i\rangle \otimes |\phi_j\rangle$ . We have this. Now we have matrix  $A$  such that  $\alpha_{ij}$  is the  $ij$ th element of matrix  $A$ . Now we will invoke something called singular value decomposition. Singular value decomposition, it states that an arbitrary  $X$  matrix of dimension  $N$  by  $M$  can be written as some  $U$ , which is a  $N$  by  $N$  unitary, some  $D$ , which is an  $N$  by  $M$  generalized diagonal matrix, and  $V$  transpose, which is  $M$  by  $M$ , another unitary. So,  $U$  is unitary.

(Refer slide time: 1:45)

→ Schmidt Decomposition.

$$|\psi\rangle = \sum_{ij} \alpha_{ij} |\psi_i\rangle \otimes |\phi_j\rangle$$
$$A = [\alpha_{ij}]$$

→ Singular value Decomposition.

$V$  is unitary. If  $V$  is unitary,  $V$  transpose is also unitary. And  $D$  is a diagonal matrix. But  $D$  is a rectangular matrix. What do we mean by diagonal?

So, of course, there can be two type of diagonals. One is this type of diagonal. Then the diagonal matrix will look like  $D_1, D_2, D_3$ , so on. And rest everything is zero. If there is a other type of the long diagonal matrix, the matrix, then we have  $d_1, d_2, d_3$  and everything else is zero. So, this is what we mean by generalized diagonal matrix.

Another interesting point about the singular value decomposition is the elements  $D_1$ , the diagonal elements  $D_2, D_3$ , they are all real and they are all positive. They can be zero,

but they cannot be negative. They are non-negative numbers. So, all the elements in D are non-negative numbers. So, this is very important decomposition and we will be using it in our present treatment.

(Refer slide time: 3:00)

$N \times M \quad X = U_{N \times N} D_{N \times M} (V^T)_{M \times M}$   
 $U \rightarrow \text{Unitary}$   
 $V \rightarrow \text{Unitary}$   
 $D \rightarrow \text{Diagonal} \quad d_1, d_2, d_3 \in \mathbb{R}_+$   
 $D_{N \times M} = \begin{bmatrix} d_1 & 0 & 0 \\ 0 & d_2 & 0 \\ \vdots & \vdots & \vdots \\ 0 & 0 & d_3 \end{bmatrix} \begin{bmatrix} u_1 & v_1 \\ \vdots & \vdots \\ u_n & v_m \end{bmatrix}$   
 $= \begin{bmatrix} d_1 & & & \\ & d_2 & & \\ & & d_3 & \\ & & & \ddots \end{bmatrix}$

So, we have a matrix A, which is  $d_1$  by  $d_2$  matrix. So, we decompose it, we find a singular value decomposition of it where  $U D V^T$ , where U is a  $d_1$  dimensional unitary, V is  $d_2$  dimensional unitary and D is the diagonal, generalized diagonal matrix. So,  $A_{ij}$  which is  $\alpha_{ij}$ , can be written as  $\sum_k U_{ik} D_{kl} V^T_{lj}$ . This is how we can decompose element wise matrix multiplication, so the element of the product can be written as the product of elements of the matrices U D V here.  $D_{kl}$  we know, it is  $d_k \delta_{kl}$  because D is a diagonal matrix. So, we can write  $\alpha_{ij}$  as  $\sum_k U_{ik} d_k \delta_{kl} V^T_{lj}$ . It is  $V^T_{lj}$ . So, in terms of V, we can write it as  $\sum_l V_{jl} U_{ik} d_k$ . So, this is the decomposition we get and we can simplify it by using the delta function. So,  $\sum_k U_{ik} V_{jk} d_k$ . This is how we can write  $\alpha_{ij}$  in terms of elements unitary U and V and the  $d_k$  is the singular values of matrix A. Now we have expression for  $\psi$  in terms of  $\alpha_{ij}$  and it is  $\sum_{ij} \alpha_{ij} \psi_i \otimes \phi_j$ , and we can substitute it here  $\sum_{ij} \sum_k U_{ik} V_{jk} d_k \psi_i \otimes \phi_j$ . Now let us say we have a vector  $e_k$  defined as  $\sum_i U_{ik} \psi_i$ .  $\psi_i$  is the orthonormal basis in first Hilbert space in  $H_{d_1}$ . Now what is  $\langle e_l, e_k \rangle$ , inner product, that will be  $\sum_i \sum_j U_{ik} \langle \psi_i, \psi_j \rangle U_{jk}$ .

(Refer slide time: 5:26)

$$D_{kl} = d_{kl} \delta_{kl}$$

$$d_{ij} = \sum_k U_{ik} d_k \delta_{kl} V_{jk}$$

$$= \sum_k U_{ik} V_{jk} d_k$$

$$|\Psi\rangle_{AB} = \sum_{ij} d_{ij} |\psi_i\rangle \otimes |\phi_j\rangle$$

I'm just using this expression for  $e_l$  and  $e_k$  and I get this. That will be, since  $\psi_i$  is the orthonormal basis, so,  $\langle \psi_i | \psi_j \rangle$  is the delta function,  $\delta_{ij}$ . So, we can sum over  $j$  and replace wherever we have  $j$  by  $i$ , we get sum over  $i$   $U_{il}^* U_{ik}$ . And this we can write as sum over  $i$   $U^\dagger_{li} U_{ik}$ , so, we are using that  $U_{il}^*$  is the element  $U^\dagger_{li}$  element of  $U^\dagger$ . Okay, this is the identity we have used.

(Refer slide time: 6:21)

$$|\Psi\rangle_{AB} = \sum_{ij} d_{ij} |\psi_i\rangle \otimes |\phi_j\rangle$$

$$= \sum_{ij} \sum_k U_{ik} V_{jk} d_k |\psi_i\rangle \otimes |\phi_j\rangle$$

$$|e_k\rangle = \sum_j U_{jk} |\psi_j\rangle$$

$$\langle e_l | e_k \rangle = \sum_{j_1 j_2} U_{j_1 k}^* U_{j_2 k} \underbrace{\langle \psi_{j_1} | \psi_{j_2} \rangle}_{\delta_{j_1 j_2}}$$

$$= \sum_j U_{jk}^* U_{jk}$$

Now we have  $U^\dagger_{li} U_{ik}$ . So, the right index and left index matches and the summation is over that matched index. So, it will be a product of the two matrices  $U^\dagger U$  and the  $lk$  element of that.  $U$  is a unitary matrix. This is the condition of the singular value decomposition.

(Refer slide time: 8:05)

$$= \sum_j U_{jk}^* U_{jk} \delta_{lj}$$

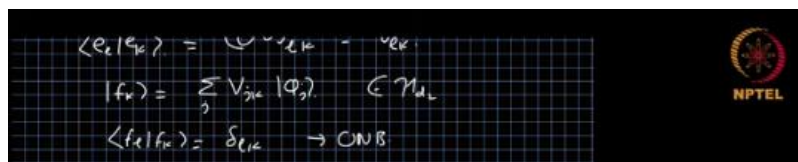

$$= \sum_j (U^\dagger)_{lj} U_{jk}$$

$$\langle e_l | e_k \rangle = (U^\dagger U)_{lk} = \delta_{lk}$$

$$|\psi_k\rangle = \sum_j V_{jk} |\phi_j\rangle \in \mathcal{M}_A$$

So,  $U^\dagger U$  is identity. So,  $U^\dagger U$   $l_k$  element is  $\delta_{lk}$ . So, from here, we can see that  $e_l, e_k$  are orthonormal states. Similarly, we can have  $f_k$ , which is sum over  $j, U, jk, V, jk$  and  $\phi_j$ , for  $H_{d2}$ . And we can verify again that  $f_l f_k$  is  $\delta_{lk}$  that means it's orthonormal basis. Why did we go through all this trouble to arrive at some expression, because this expression is, means  $\psi_{AB}$  can be written as sum over  $k, d_k, e_k$  tensor  $f_k$ , where,  $e_k$  is an orthonormal basis and  $f_k$  is an orthonormal basis in  $H_{d2}$ . And  $d_k$ s are real and positive non-negative numbers. So, this decomposition is the canonical representation of the state  $\psi$ . This is the minimum you can achieve in terms of number of terms. And this is called Schmidt decomposition.

(Refer slide time: 8:30)

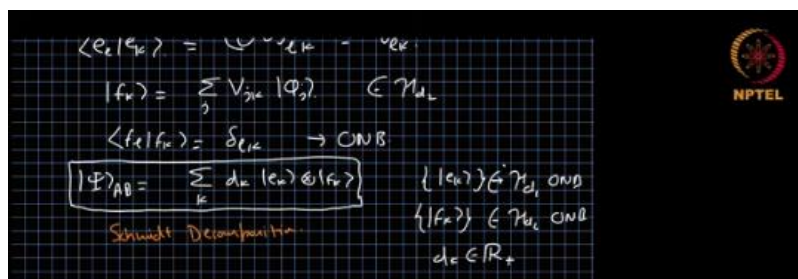

$$\langle e_l | e_k \rangle = \sum_j U_{lj} U_{kj}^* = \delta_{lk}$$

$$|f_k\rangle = \sum_j V_{jk} |\phi_j\rangle \in \mathcal{H}_{d_2}$$

$$\langle f_l | f_k \rangle = \delta_{lk} \rightarrow \text{ONB}$$

Now, you see we have a set of these. They are the singular values of the coefficient matrix  $A$ , then, the number of non-zero  $d_k$ s is same as the rank of matrix  $A$ . It means if only the first one or only one  $d_k$  is non-zero and all other  $d_k$ s are zero, Then we have a product state, then  $\psi$  can be written as, if we keep these in the descending order, so, the largest one is non-zero and that is equal to 1, so, it becomes  $e_1$  tensor  $f_1$ . So, from this decomposition, we will immediately get the product form of the state  $\psi$ . But, if we have more than one  $d_k$  non-zero then uh the state  $\psi$  cannot be written in this form, then the state  $\psi$  will be this is when rank is one rank of  $A$  is one, when the rank of  $A$  is not one then  $\psi$  will be at least  $e_1$  tensor  $f_1$  with coefficient  $d_1$  plus  $d_2 e_2 f_2$  and other terms.

(Refer slide time: 9:08)

$$\langle e_l | e_k \rangle = \sum_j U_{lj} U_{kj}^* = \delta_{lk}$$

$$|f_k\rangle = \sum_j V_{jk} |\phi_j\rangle \in \mathcal{H}_{d_2}$$

$$\langle f_l | f_k \rangle = \delta_{lk} \rightarrow \text{ONB}$$

$$\boxed{|\Psi\rangle_{AB} = \sum_k d_k |e_k\rangle \otimes |f_k\rangle}$$

Schmidt Decomposition

$$\begin{aligned} \{ |e_k\rangle \} &\in \mathcal{H}_{d_1} \text{ ONB} \\ \{ |f_k\rangle \} &\in \mathcal{H}_{d_2} \text{ ONB} \\ d_k &\in \mathbb{R}_+ \end{aligned}$$

(Refer slide time: 10:16)

So, in that case, it is guaranteed that it is not a separable state. In that way, Schmidt decomposition will give us very quickly, will tell us whether a given state is a separable or an entangled state. The number of non-zero  $d_k$ 's are also called the Schmidt rank. The number of non-zero  $d_k$ 's, they are called, they are also called Schmidt rank. Now we will discuss operators acting on  $H_{d1}$  tensor  $H_{d2}$ , so they belong to the set of operators acting on  $H_{d1}$   $H_{d2}$ . So, if  $T$  is the operator acting on  $H_{d1}$  and  $S$  is the operator acting on  $H_{d2}$ , then we represent the operator  $Z$ , which is  $T$  tensor  $S$ , we will define what we mean by tensor here, that will act, that will belong to  $H_{d1}$  tensor  $H_{d2}$ .

(Refer slide time: 12:51)

So, if we apply  $Z$  on the state  $\psi$  and let us say  $\psi$  is the product state, then  $T$  tensor  $S$   $\psi$  tensor  $\phi$ , so till now there is no correlation, there is nothing here to worry or to consider. So the operator of subsystem  $A$  will act on the state of subsystem  $A$  and operator on subsystem  $B$  will act on state of subsystem  $B$ . So, it will be  $T$   $\psi$  tensor  $S$   $\phi$ . So, this is how the tensor product operators acting on the tensor product state is defined. So, now if we have the more general state, which is sum over  $ij$ ,  $\alpha_{ij}$ ,  $\psi_i$  tensor  $\phi_j$ . Since the matrix product is linear, then  $T$  tensor  $S$ , acting on  $\psi$  will be sum over  $ij$ ,  $\alpha_{ij}$ ,  $T$ ,  $\psi_i$  tensor  $S$   $\phi_j$ . it will individually on each of the tensor product it

will act in this way. T is the operator on subsystem A and if we don't apply any operator on subsystem B that is represented by T tensor identity.

(Refer slide time: 14:11)

$$| \Psi \rangle = \sum_j d_j | \psi_j \rangle \otimes | \phi_j \rangle$$

$$T \otimes I | \Psi \rangle = \sum_j d_j T | \psi_j \rangle \otimes I | \phi_j \rangle$$

$$\rightarrow [T \otimes I, I \otimes S] = 0$$

Identity means doing nothing on a subsystem. Similarly, identity tensor S will represent the operator acting only on subsystem B, nothing on subsystem A. And these two operators always come. The operator acting only on subsystem A and operator acting only on subsystem B, they commute. If we have A, operator A and the elements are a11, a12, a13, a21, a22 and so on, we have an operator with these elements and if we have another operator with elements b11, b12, b21, b22 and all these elements then A tensor B, is defined as a bigger matrix so till now we did not mention the dimension of A and B, it can be any dimension, they can be square they can be rectangular they can be even vectors, so we have already seen the tensor product with vectors a11 times B, a12 times B, a13 times B and so on. a21 times B, a22 times B a23 times B and so on and so on.

(Refer slide time: 16:37)

$$A = \begin{bmatrix} a_{11} & a_{12} & a_{13} & \dots \\ a_{21} & a_{22} & \dots & \dots \\ \vdots & \vdots & \vdots & \vdots \end{bmatrix}$$

$$B = \begin{bmatrix} b_{11} & b_{12} & \dots & \dots \\ b_{21} & b_{22} & \dots & \dots \\ \vdots & \vdots & \vdots & \vdots \end{bmatrix}$$

$$A \otimes B = \begin{bmatrix} a_{11}B & a_{12}B & a_{13}B & \dots \\ a_{21}B & a_{22}B & \dots & \dots \\ \vdots & \vdots & \vdots & \vdots \end{bmatrix}$$

This is how we define the tensor product we can make some grid here to understand it slightly better. The dimension of this grid is same as this block is same as the dimension of B, so if you write just this block, it will be a11 b11 a12 a11 b12 a11 b13 and so on a11, b21, a11, b22, a11, b23 and so on and so on. a11, b21, a11, b22, a11, b23 and so on.

This is just this block. So, here we have taken the B matrix and multiplied every element with number a11.

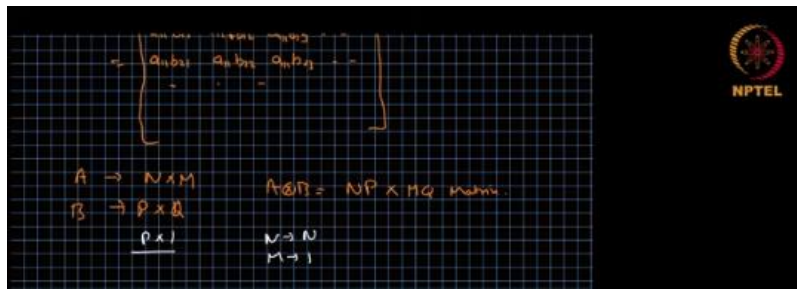

(Refer slide time: 16:44)

Similarly, in this block, we have the whole B matrix and multiply those elements with  $a_{12}$  and so on. So, these lines, these blocks are just to understand. But ultimately we have a much bigger matrix. And the dimension of matrix is defined like this. If A is N by M matrix and B is P by Q matrix, then A tensor B will be NP by MQ matrix.

This is how the dimensions multiply. For example, if n is the one-dimensional vector, so, it means A is the one-dimensional vector. So, if M equals N is N and M is 1, so it is N by 1 matrix and P is also N by 1, P by 1 matrix. Then A tensor B will also be a vector and the dimension of it will be NP times 1. NP by 1.

(Refer slide time: 17:33)

And this example we have seen already when we define the tensor product of states. So, in that way the definition of tensor product is same for operators and states if we consider states as one-dimensional matrices. Now if we have A tensor B and we want to find the element MN here. So, of course, A tensor B is a matrix and finding MN element is a very well-defined question here. But it will be much more useful notation if instead of mn element, if we say ij kl element.

So, what we have done is  $m$  we are writing as  $ij$  and  $n$  we are writing as  $kl$ . So, for example if our  $A$  is a 2 by 2 matrix and  $B$  is also 2 by 2 matrix, then  $A$  tensor  $B$  is a 4 by 4 matrix so instead of  $m$  going from 1 to 4,  $m$  and  $n$  both going from 1 to 4, we are saying  $m$  is 1 1, 1 2, 2 1 and 2 2, similarly,  $n$  is 1 1, 1 2, 2 1 and 2 2. We just change the notation from the decimal we have gone to whatever is the convenient basis here, the  $ij$ . So,  $i$  and  $j$  can be from 1 to  $d_1$  and 1 to  $d_2$ , respectively. So, you will see in time how this will be a more useful representation for an element. Now we are seeing  $A$  tensor  $B$ ,  $ij, kl$  element. So,  $A$ , we can write as, we can open it in some basis,  $A_{ij}$ , let me say  $i, k$ .

(Refer slide time: 18:52)

So, we can write matrix  $A$  in terms of the computational basis  $i$ , which is 0, 0 and 1 at the highest place and 0, 0 everywhere. Then  $k$  is also like that. So,  $A$  matrix can be expanded in terms of the coefficient  $A_{ik}$  and the basis  $i$ , the computational basis. Similarly,  $B$ , we can define as  $B_{jl}$ ,  $j$  outer product  $l$ . Let me put a bar here to say that they do not need to be from the same Hilbert space.

(Refer slide time: 20:17)

But we can always find a computational basis in both the vector spaces. Then  $A$  tensor  $B$  will be sum over, this was summation is over  $ik$ , this summation is over  $jl$ . So,  $ik, jl$ , all four summations we have here, that will be a  $ik, ik$  tensor  $B_{jl}, j$  bar  $l$  bar. We can reorganize the symbols  $ij, kl$ , a  $ik, bj, l$ , they are scalar, they come out on one side. We have  $ik$  tensor  $jl$ . So, we have the operator of subsystem  $A$  and the operator of the subsystem  $B$ . I should not say  $A$  and  $B$  to avoid the confusion. But this we have operator

of A and this is operator of B. This can be written as  $ij\ kl$   $a_{ik} b_{jl}$ ,  $i$  tensor  $j$  and  $k$  tensor  $l$ ,  $j$  bar and  $l$  bar. So it becomes  $ij\ kl$ .

(Refer slide time: 22:31)

$$\begin{aligned}
 A \otimes B &= \sum_{i,k} a_{ik} |i\rangle\langle k| \otimes \sum_{j,l} b_{jl} |j\rangle\langle l| \\
 &= \sum_{i,j,k,l} a_{ik} b_{jl} |i\rangle\langle k| \otimes |j\rangle\langle l| \\
 &= \sum_{i,j,k,l} a_{ik} b_{jl} |ij\rangle\langle kl| \\
 A \otimes B &= \sum_{i,j,k,l} \eta_{ij,kl} |ij\rangle\langle kl| \\
 \boxed{\eta_{ij,kl} = a_{ik} b_{jl}}
 \end{aligned}$$

So,  $a_{ik} b_{jl}$ ,  $i, j, k, l$  and let us call it  $\eta_{ij,kl}$ ,  $i, j, k, l$ , sum over  $i, j, k, l$ , where we have to redefine  $\eta_{ij,kl}$  to be  $a_{ik} b_{jl}$ . And this is  $A$  tensor  $B$ , the whole matrix  $A$  tensor  $B$ . Now, if we compare this with this definition so we had a computational basis  $i, j, k$  and computational basis of  $B$  was  $j, l$  and  $A$  can be written as  $i, k$  and  $a_{ik}$  and this becomes the  $i$ th element from here.  $a_{ik}$  is small  $a_{ik}$ . The  $i$ th element of the matrix  $A$  is just a  $i, k$ , the coefficient of  $i$  outer product  $k$ . Similarly,  $B_{j,l}$  element is just  $b_{j,l}$ . So if we compare this representation with this, so here the computational basis is  $i, j$ , so this becomes the orthonormal basis in  $H_{d1}$  tensor  $H_{d2}$  and this is the orthonormal basis. So, the element what we were looking for that is  $A$  tensor  $B$   $ij, kl$  element is actually  $\eta_{ij,kl}$  and  $kl$ , because this is the coefficient in the computational basis. And this is nothing but a  $ik$  and times  $b_{jl}$ .

(Refer slide time: 23:54)

$$\begin{aligned}
 A \otimes B &= \sum_{i,j,k,l} \eta_{ij,kl} |ij\rangle\langle kl| \quad \left\{ \begin{array}{l} \text{basis} \\ \text{on } A \otimes B \end{array} \right. \\
 \boxed{\eta_{ij,kl} = a_{ik} b_{jl}} \\
 (A \otimes B)_{ij,kl} &= \eta_{ij,kl} = a_{ik} b_{jl}
 \end{aligned}$$

Just look at the indices. Indices are very important here. The  $ij\ kl$  element is not a  $ij$  and  $b_{kl}$ . It's  $a_{ik}$  and  $b_{jl}$  times  $b_{jl}$ . So, there is a small shuffling of the indices here to get the  $ij\ kl$  element of the tensor product.

This will become very important with time and when we talk about the positive and non-positive, completely positive maps, when we talk about those things or the Kraus operators and super operators, these indices will become very, very important. One can figure out after doing this thing, it's not very difficult to check that A tensor B times C tensor D is actually A times C tensor B times D. I call it A B C D rule. I don't know if there is a rule, a name for this rule but it is very very useful. This is, this we have already used multiple times without without us realizing for example when we when we said T tensor S acting on psi tensor phi is T psi tensor S phi. We have actually used this rule precisely. Further, when we said ij tensor ik tensor j bar l bar is equal to i tensor j bar times k tensor l bar, we have used this rule but in reverse, we were given this and we took it to this.

(Refer slide time: 25:18)

$$(A \otimes B)_{rs, x\ell} = y_{rs, x\ell} = a_{rx} b_{s\ell}$$

$$\rightarrow (A \otimes B)(C \otimes D) = AC \otimes BD \quad \checkmark$$

$$(\psi \otimes S)(|u\rangle \otimes |\phi\rangle) = T|u\rangle \otimes S|\phi\rangle$$

So, in that way, without us realizing we have used this rule multiple times and when we work with tensor products space, this rule will appear multiple times and we will use it without registering it in our mind. So, these are the properties of the tensor product of operators and there is the exercise, this can be fun exercise and slightly involved. If I define the matrix H, H tensor identity plus identity tensor H. And H is Hermitian. So, calculate the unitary, which is exponential of minus i H T over h bar. You can use small u, which is exponential of minus i small h T over h bar. So, we have to calculate this in terms of u.

(Refer slide time: 26:44)

$$(\psi \otimes S)(|u\rangle \otimes |\phi\rangle) = T|u\rangle \otimes S|\phi\rangle$$

$$(|x\rangle \otimes |y\rangle) = (|xy\rangle) \quad (|x\rangle \langle z|)$$

→ Exercise:  $H = h\sigma_z + \eta\sigma_x$

Calculate:  $U = e^{-iHt/\hbar}$

$u = e^{-iht/\hbar}$
