Quantum Maps: Completely Positive Maps - Part 01

Today we will be discussing completely positive maps. This is in sequence, in continuation with the positive maps and stuff we have been studying so just to recapitulate a positive map, ω is something which takes positive operators to positive operators. So, ρ is a positive operator it means its eigenvalues are positive semi-definite. We mean when we say positive, we can mean positive definite or positive semi-definite, it's a very small difference for us but in mathematics it can be a big difference, but we are not worried about that for the moment. So, ρ is a positive operator so that eigenvalues are positive and ρ is Hermitian and it will be mapped to another operator ρ' which has a similar property that its eigenvalues are positive and its Hermitian. So, a positive map is Hermitian as well as positivity preserving. Now what will happen if we apply this map ω which is a positive map on one subsystem, on of a larger system. So, if we are applying ω on subsystem B and nothing on subsystem A, so we can write it as $I \otimes \omega$ means applying nothing identity operation and if we apply it on a bipartite state ρ_{AB} , so ρ_{AB} is the state of a mixed state or pure state doesn't matter, it's the state of a of a bipartite system of a composite system. So, what will happen if we do that will it still be a positive map. So will ω still map positive operators to positive operators. So, the question is if identity tensor ω maps ρ_{AB} to ρ'_{AB} , some other state of the same subsystem.

(Refer slide time: 1:28)

Completely positive Maps:

$$\text{true map } \mathcal{Q}: \rho \rightarrow \rho'$$
$$\rho \succ 0 \quad \text{eig}(\rho) \succ 0 \quad \rho = \rho^\dagger$$
$$\rho' \succ 0 \quad \text{eig}(\rho') \succ 0 \quad \rho' = \rho'^\dagger$$

The slide features a grid background and the NPTEL logo in the top right corner.

To see that, let us take example, let us say rho AB is in the separable space. It means rho AB can be written as sum over n, p n rho A n tensor rho B n, where p n are positive numbers such that they add up to 1. It means sum over n p n equals 1. and rho A n is a positive operator, which represent a density matrix in a subsystem A and rho B n is a positive operator representing a density operator in subsystem B. So, when we apply the positive map omega on one side of rho AB on one subsystem of rho AB, then it will be it can be written as p n rho A n, means nothing on A n tensor omega acting on rho B n. So, if omega is positive and it is positive then rho B n will be rho prime B n which are also positive operators. So, it means the transformed state rho tilde AB which is this here, is nothing but sum over n p n rho A n tensor rho B n prime.

(Refer slide time: 2:49)

$\rho \succ 0 \implies e_{ij}(\rho) \succ 0 \quad \rho = \rho^\dagger$
 $\rho' \succ 0 \implies e_{ij}(\rho') \succ 0 \quad \rho' = \rho'^\dagger$
 $(\mathbb{1}_A \otimes \omega_B)(\rho_{AB})$
 $\mathbb{1}_A \otimes \omega_B : \rho_{AB} \rightarrow \rho'_{AB}$
 $\rho_{AB} = \sum_n p_n \rho_{A_n} \otimes \rho_{B_n}$
 $p_n \succ 0 \quad \sum_n p_n = 1$

It's a state rho A n rho prime B n, p n, all of those are valid things, whatever we needed. And needed instance like this is a valid state of a system B, this is a valid state of a subsystem A. So, the total thing is a valid state, then we are taking the mixture of these valid states. So, this is also a valid state. it is possible that omega is just positivity preserving positive map but not just preserving in that case this will have different trace so it will be a unnormalized valid state but still a positive operator and we can normalize it and we can get a state we want so in that way identity tensor omega acting on rho AB results in a positive operator rho prime AB. But this is the case when rho AB is a separable state because we were writing rho AB as sum over n p n rho A n tensor rho B n and we have already discussed that these kinds of states are called separable states.

(Refer slide time: 5:01)

$$p_n \geq 0 \quad \sum_n p_n = 1$$

$$p_{A_n} \geq 0 \quad p_{B_n} \geq 0$$

$$(\mathbb{1} \otimes \Omega) \rho_{AB} = \sum_n p_n \rho_{A_n} \otimes \Omega(\rho_{B_n})$$

$$\Omega(\rho_{B_n}) = \rho'_{B_n} \geq 0$$

$$\rho'_{AB} = \sum_n p_n \rho_{A_n} \otimes \rho'_{B_n} \quad \text{unnormalized Valid State.}$$

$$(\mathbb{1} \otimes \Omega) \rho_{AB} \rightarrow \rho'_{AB}$$

So, there's no wonder that a positive map goes to positive map because the matrix representation or like it's not because but we can get a hint that this will be true from the matrix representation of omega, the matrix representation of omega was M and from here we went to H and we know about one, what we know about H is it's positive, if we have psi tensor phi H phi tensor psi, this quantity is always positive. So, the H matrix corresponding to a positive map is always positive for all the product states and separable states is just a mixture of product states. So, in that way, we can get a hint that probably this statement is always true. What we want is, is it always true, is it always that, I tensor omega acting on rho goes to rho prime always positive for all rho positive. If rho omega bar goes to rho bar prime positive for all rho bar positive, it means is it always true that if omega is a positive map, then it acting on a subsystem of a composite system will also be a positive map. Now, a general proof might be very difficult, but one counter example should be enough to prove that this is not the case. So, the example we have, our counter example is a transfer map.

(Refer slide time: 6:50)

$$\rho_{AB} = \sum_n p_n \rho_{A_n} \otimes \rho_{B_n} \rightarrow \text{Separable states}$$

$$\Omega: M \rightarrow H \rightarrow \langle \alpha | \langle \psi | H | \psi \rangle | \alpha \rangle \geq 0$$

$$\rightarrow (\mathbb{1} \otimes \Omega) \rho \rightarrow \rho' \geq 0 \quad \forall \rho \geq 0$$

$$\Omega(\bar{\rho}) \rightarrow \bar{\rho}' \geq 0 \quad \forall \bar{\rho} \geq 0$$

So, transpose map takes rho to rho transpose. If rho is positive, then rho transpose is positive. If we apply identity tensor transpose map on rho AB, which is sum over n p n,

which is a separable state, if we apply it on a separable state, ρ_B transpose, then this also is positive. So, it satisfies all the properties so far of a positive map. So, transposition is a positive map but what will happen if we apply it on a state which is not a separable state, so let us take a state $|\psi\rangle$ which is $\frac{1}{\sqrt{2}}(|01\rangle - |10\rangle)$. Okay, so in a vector form it will be $\frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ 1 \\ -1 \\ 0 \end{pmatrix}$. So, the density matrix corresponding to this will be $\frac{1}{2} \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$.

(Refer slide time: 8:05)

→ Example: Transpose Map.

$$\rho \rightarrow \rho^T \quad |\psi\rangle \rightarrow \rho^T |\psi\rangle$$

$$(\rho^T)_{AB} = \sum_n b_n \rho_{An} \otimes \rho_{Bn}^T$$

→ $|\psi\rangle = \frac{1}{\sqrt{2}}(|01\rangle - |10\rangle)$

(Refer slide time: 8:45)

$$= \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ 1 \\ -1 \\ 0 \end{pmatrix}$$

$$\rho = \frac{1}{2} \begin{pmatrix} |01\rangle\langle 01| + |10\rangle\langle 10| & \\ & -|01\rangle\langle 10| - |10\rangle\langle 01| \end{pmatrix}$$

$$= \frac{1}{2} \begin{pmatrix} |0\rangle\langle 0| \otimes |1\rangle\langle 1| + |1\rangle\langle 1| \otimes |0\rangle\langle 0| & \\ & -|0\rangle\langle 1| \otimes |1\rangle\langle 0| - |1\rangle\langle 0| \otimes |0\rangle\langle 1| \end{pmatrix}$$

We can write it in a simpler form which will be you see here we have $|0\rangle\langle 0|$ tensor $|1\rangle\langle 1|$ and $|1\rangle\langle 1|$ tensor $|0\rangle\langle 0|$ here, so it can be written as $|0\rangle\langle 0|$ tensor $|1\rangle\langle 1|$ plus similarly here, one outer product one tensor zero outer product zero and this term here minus zero outer product one tensor one outer product zero minus one outer product zero tensor zero outer product one. So, when we take partial transpose over this state ρ_{AB} , this is the ρ_{AB} , we have then it will be the transposition on the second subspace so transposition on one one it will remain one one zero and one real state so there is no complex conjugate coming here one one tensor zero zero will remain

zero zero minus one zero or zero one tensor one zero will become zero one after taking transposition minus one zero tensor one zero. So, this is our state or this is our matrix after transposition now we can write it and this can be a decent exercise problem that this matrix will look like the following, just I'm putting the grids to this is, minus one minus one and this is one one all other are zero. So, this is our matrix after applying partial transposition and we can see that the eigenvalues of this are plus half and minus half, plus half appears three times and minus half appears once. So, these are the eigenvalues of this matrix.

(Refer slide time: 10:52)

$$(I \otimes T)(\rho_{AB}) = \frac{1}{2} \left[|0\rangle\langle 0| \otimes |1\rangle\langle 1| + |1\rangle\langle 1| \otimes |0\rangle\langle 0| - |0\rangle\langle 0| \otimes |0\rangle\langle 0| - |1\rangle\langle 1| \otimes |1\rangle\langle 1| \right]$$

$$= \frac{1}{2} \begin{bmatrix} 0 & 0 & 0 & -1 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -1 & 0 & 0 & 0 \end{bmatrix}$$

So, in that way identity tensor transpose acting on a subsystem of a larger system need not be a positive operator even if even if rho AB is positive. So, this is one counter example where we see that not all the positive maps which map positive operator to positive operator are positive maps, when we apply them on a subsystem of a larger system. So, it means even if rho is positive does not imply that identity tensor omega is positive. It means if omega is positive does not mean that identity tensor omega is a positive map. So, here we define a new operator.

(Refer slide time: 11:34)

$$= \frac{1}{2} \begin{bmatrix} 0 & 0 & 0 & -1 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -1 & 0 & 0 & 0 \end{bmatrix}$$

$$\text{eigen}(\rho_{AB}) = \frac{1}{2}, \frac{1}{2}, \frac{1}{2}, -\frac{1}{2}$$

$(I \otimes T) \rho_{AB} \not\geq 0$ Positive operator; $\rho_{AB} \geq 0$

$$\underline{\Omega \geq 0} \not\Rightarrow \underline{(I \otimes \Omega) \geq 0}$$

We call it m positive map. M positive maps are those maps, where, we have identity, we have a subsystem which is m dimensional and our map ω , this is positive for ω positive. If you have a map which is positive map ω , it is also positive when we apply it on a bipartite system, one side of the bipartite system where the other party is m dimensional then it is called a m positive map. But we are not interested in that. We are interested in the completely positive maps. Completely positive map is a m positive map for all m . If we have a map ω , which is positive and it is m positive for all the values of m , then it is a completely positive map.

(Refer slide time: 13:19)

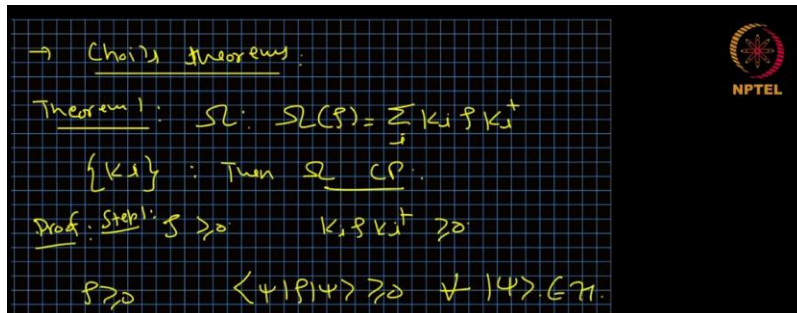

So, let me repeat if we have a map ω which is positive and $1_m \otimes \omega$ is also positive for all m then it is called a completely positive. So, the benefit or advantage of a completely positive map is that a completely positive map ω or completely positive or CP we will often say a completely positive or CP map ω is, will map density matrices to density matrices no matter on what subsystem on what system on what dimension we are applying them. So, a completely positive map will always map positive operators to positive operators. Hence, all the physical processes can be represented by a CP map. Because a physical process will always take a state of a quantum system and it will map to another state of a quantum system.

(Refer slide time: 15:20)

So, in that way, it's a process, it's a map which maps positive operator to positive operator and hence it can be represented by a completely positive map. An arbitrary completely positive map can be thought of as a physical process or in simpler words, if we have an arbitrary completely positive map then we can always find a physical process representing that map. So, in that way, completely positive maps represent physical processes and physical processes can be represented by a completely positive map. In that way, the set of completely positive maps is equivalent to the set of all the physical processes we can perform on a quantum system. There are some very interesting theorems, demonstrating these concepts, proving these concepts so and making them more formal. So, they are called choi's theorems.

(Refer slide time: 17:18)

There are two theorems and the theorem one, the first theorem states that that if we can write the action of this map on an operator rho as some more $\sum_i K_i \rho K_i^\dagger$, for an arbitrary set of operators K_i , then this map Ω must be completely positive. Let me repeat it. If we are given a map such that the action of this map on an operator rho can be written as $\sum_i K_i \rho K_i^\dagger$. For an arbitrary set of operators K_i , then Ω must be a completely positive map. Proof is reasonably straightforward.

First, we see that if rho is positive, then $K_i \rho K_i^\dagger$ is also positive. Let us call it step one. Okay, so how do we prove that the definition of positivity rho being positive is that its expectation value is positive for all the states psi in the Hilbert space. Now, if we have rho prime, which is $K_i \rho K_i^\dagger$, then $\langle \psi | \rho' | \psi \rangle$ which is equal to $\langle \psi | K_i \rho K_i^\dagger | \psi \rangle$, let us call them phi rho phi and K_i need not be unitary, they can be any arbitrary operator. So, phi need not be normalized, so we can put a normalization constant n outside so that phi is normalized and n is a normalization constant, so it's the positive number. And we know that rho is a positive operator, so phi rho phi is also a

positive operator, so this is always positive for all the ψ 's. Hence for all the ψ 's and hence for all the K i's so this implies that $K_i \rho K_i^\dagger$ is a positive operator good.

(Refer slide time: 18:19)

$$P = \sum_i K_i \rho K_i^\dagger \rightarrow \langle \psi | P | \psi \rangle$$

$$= \langle \psi | \sum_i K_i \rho K_i^\dagger | \psi \rangle$$

$$= \sum_i \langle \psi | K_i \rho K_i^\dagger | \psi \rangle \geq 0 \quad \forall |\psi\rangle$$

$$\Rightarrow \boxed{K_i \rho K_i^\dagger \geq 0}$$

Step 2:
$$\sum_i K_i \rho K_i^\dagger \geq 0$$

Step two, sum over i $K_i \rho K_i^\dagger$ is positive, of course some of the positive operator is also a positive operator, so we don't know, there's nothing to prove here. Step three, Identity tensor ω acting on ρ is ρ_{AB} let us say, bipartite system is sum over i identity tensor $K_i \rho K_i^\dagger$ there is nothing to prove here also this is the definition of the map ω and the partial implementation of it so if ρ_{AB} is a positive operator. So, is identity tensor $K_i \rho_{AB} K_i^\dagger$ and hence sum over i , identity tensor $K_i \rho_{AB} K_i^\dagger$ positive and here we have not assumed anything about ρ_{AB} other than the fact that it is a positive operator. This implies that if ω of ρ is sum over i , $K_i \rho K_i^\dagger$, then identity tensor ω acting on ρ_{AB} is positive for all ρ_{AB} positive. Hence, ω is a completely positive number.

(Refer slide time: 20:15)

Step 3:
$$(\mathbb{1} \otimes \omega) \rho_{AB} = \sum_i (\mathbb{1} \otimes K_i) \rho_{AB} (\mathbb{1} \otimes K_i^\dagger)$$

$$\rho_{AB} \geq 0 \Rightarrow (\mathbb{1} \otimes K_i) \rho_{AB} (\mathbb{1} \otimes K_i^\dagger) \geq 0$$

$$\sum_i (\mathbb{1} \otimes K_i) \rho_{AB} (\mathbb{1} \otimes K_i^\dagger) \geq 0$$

$$\Rightarrow \text{if } \omega(\rho) = \sum_i K_i \rho K_i^\dagger$$

$$\Rightarrow (\mathbb{1} \otimes \omega) \rho_{AB} \geq 0 \quad \forall \rho_{AB} \geq 0$$

Hence ω is a CP map.

So, that's the proof of the first theorem. Now the second theorem. If we have a CP map, ω , then there exists a set of operators K_i such that $\omega(\rho)$ can be written as $\sum_i K_i \rho K_i^\dagger$. So, the second theorem says that for every completely positive map, the representation $\sum_i K_i \rho K_i^\dagger$ exists. It means we can always find a set of operators K_i such that $\omega(\rho)$ can be written as $\sum_i K_i \rho K_i^\dagger$.

(Refer slide time: 21:13)

This is called operator sum representation or Kraus operator representation and the proof of this goes as follows. Since ω is a CP map, then identity tensor ω is also completely positive. Now, first let me say, let's start with the computational basis $|i\rangle$, and what do we mean by computational basis that i vector is zero, vector of zeros and exactly one one at i th position and rest zeros. Okay, so we have a computational basis and we can define computational basis of the bipartite system it will be $|i\rangle \otimes |j\rangle$ where i and j runs from 1 to n or d . What is the dimension, whatever is the dimension and we are assuming the bipartite system has two parties of equal dimensions here. Now, we can define a state or a vector. So, normalization for our proof, the normalization does not matter here, but we just say we have a vector here, which is $\sum_i |i\rangle \otimes |i\rangle$, so it is $|i\rangle \otimes |i\rangle$.

(Refer slide time: 23:06)

Later on, we will realize that this is an entangled state, unnormalized or maximally entangled state actually. But for the time being, that is irrelevant, so from here we can define operator E which is $|\psi\rangle\langle\psi|$. Since it is operator E which is $|\psi\rangle\langle\psi|$, so E is a positive operator. We can see that it is a positive operator because again like for any ϕ , $\langle\phi|E|\phi\rangle$ it will be $\langle\phi|\psi\rangle\langle\psi|\phi\rangle$ which is $|\langle\phi|\psi\rangle|^2$ which is a positive number or 0. So, in that way E is a positive operator. Now, we come back to our completely positive map. So, if we apply ω on one side of E , if it is a positive operator, then from there, we can say something about the representation of the ω that is the operator sum representation $\sum_i K_i \log K_i$. So, we have to prove that ω acting on E is positive, but how that will result in K_i 's? will that also we have to answer eventually. So, first before going there, we need to see over the structure of E . E can be written as $\sum_{i,j} |i\rangle\langle j| \otimes |i\rangle\langle j|$. This is what it means by taking the outer product of $|\psi\rangle$ with itself. And if we simplify it, it will be $\sum_{i,j} |i\rangle\langle j| \otimes |i\rangle\langle j|$.

(Refer slide time: 23:48)

$$\begin{aligned} \rightarrow E &= |\psi\rangle\langle\psi| \\ \langle\phi|E|\phi\rangle &= \langle\phi|\psi\rangle\langle\psi|\phi\rangle \\ &= |\langle\phi|\psi\rangle|^2 \geq 0 \\ E &= \sum_{i,j} |i\rangle\langle j| \otimes |i\rangle\langle j| = \sum_{i,j} |i\rangle\langle j| \otimes |i\rangle\langle j| \\ W &\in \mathcal{B}(\mathcal{H}_A \otimes \mathcal{H}_B) \\ W &= \sum_i A_i \otimes B_i \\ A_i &= \sum_{n,m} c_{nm}^{(i)} |n\rangle\langle m| \end{aligned}$$

So, to understand, to appreciate the structure of E , first we notice that if we have any arbitrary operator W , which acts on the set of operators, which belongs to the set of operators acting on \mathcal{H}_A tensor \mathcal{H}_B , then this W can be written as some over i , A_i tensor B_i . So, A_i s are the operator acting on \mathcal{H}_A and B_i s are the operator acting on \mathcal{H}_B . Now, any matrix A , the A_i here, for example, can be written as sum over n, m , small a, nm , n outer product m . So, in this, if n is a computational basis, then $|n\rangle\langle m|$, is the

coefficient of matrix A_i . Let me put i as somewhere here. Then A_i $n \times m$ is the coefficient of matrix A_i at a location $n \times m$.

So, we have matrices, we have locations at 1, 1, 1, 2, 1, 3 and so on. So, this will be the element at $n \times m$ location. So, if similarly, we can write for B but we don't need to here, so W becomes sum over $n \times m$ i , if we substitute for a i here then it will be it will be n outer product m tensor a_i $n \times m$ b_i , the summation i can go inside this so we can write it as sum over $n \times m$, n outer product m tensor B_{nm} . The B_{nm} is an operator acting on Hilbert space B . B_{nm} is nothing but sum over i a_i $n \times m$ B_i . So, what is the advantage of this?

(Refer slide time: 26:52)

$$W = \sum_{n,m} |n\rangle\langle m| \otimes \left(\sum_i a_{nm}^i B_i \right)$$

$$= \sum_{n,m} |n\rangle\langle m| \otimes B_{nm}$$

$$B_{nm} = \sum_i a_{nm}^i B_i$$

It means we can write W as a matrix of matrices. I'm just putting this grid for the reference purpose. So, this W can be written as a matrix of matrices where each element is a matrix here, which is B_{11} , B_{12} , B_{13} , B_{14} , B_{21} , B_{22} and so on. So, this block, if we write just along this block, it will be one outer product one tensor B_{11} . Similarly, ij th block will be i outer product j tensor B_{ij} .

(Refer slide time: 27:35)

$$B_{nm} = \sum_i a_{nm}^i B_i$$

$$W = \begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix}$$

So, it means an arbitrary operator W can be written as the location of the block tensor the block matrix. So, going back to our E . E , which was i outer product j tensor i outer product j , sum over ij says that in the ij th block, the matrix is ij and ij is a matrix with

one at ij th location and zeros everywhere else. So, this is the special matrix in that sense. Okay, and it will be useful for our proof. Now, if we apply the completely positive map on E , it will be sum over ij , i outer product j , tensor omega acting on ij .

(Refer slide time: 29:30)

$$E = \sum_{ij} |i\rangle\langle j| \otimes B_{jj}$$

$$(1 \otimes \Omega) E = \sum_{ij} |i\rangle\langle j| \otimes \Omega(|i\rangle\langle j|) \geq 0$$

$$E' \geq 0 \Rightarrow E' = E'^{\dagger}, c_{ij}(E') \geq 0$$

So, we do not know what is the exact action of omega on ij element. But we know for sure, the only thing we know is since omega is a completely positive map and since E is a positive operator, then i tensor omega acting on E is also a positive operator. Let us call it E prime. So, E prime is a positive operator. The property of a positive operator is, E prime is Hermitian and the eigenvalues of E prime are positive semidefinite.

(Refer slide time: 30:20)

$$E' = \sum_n d_n |s_n\rangle\langle s_n|$$

$d_n > 0$
 $|s_n\rangle \rightarrow$ eigenvect
 $d_n \rightarrow$ Eigenvalue.

What does it mean? It means that. It means that E prime possess a spectral decomposition sum over n , λ_n , $|s_n\rangle\langle s_n|$. Where s_n are the eigenvectors and λ_n are the eigenvalues. Since E prime is a positive operator, λ_n 's are positive semi-definite and s_n are the orthonormal basis.

(Refer slide time: 31:39)

$$E' = \sum_n d_n \begin{bmatrix} |u_{n1}\rangle \\ |u_{n2}\rangle \\ \vdots \\ |u_{nk}\rangle \end{bmatrix} \begin{bmatrix} \langle u_{n1}| & \langle u_{n2}| & \dots & \langle u_{nk}| \end{bmatrix}$$

Now let us take S_n and since we know E prime is a d square dimensional matrix because we have chosen each subsystem of d dimensions, then s_n is a d square dimensional vector. So, it is a vector d square dimensional. Let us say we have first d element, we call it a vector u_1 or u_{n1} , the next d element we call u_{n2} vector and so on. They are all normalized, the u_{nd} , the d element vectors of d dimension each, we have and we are calling them u_{n1} u_{n2} u_{n3} and so on. Okay, we are just writing them for the time being, for the ease of calculation, so E prime becomes $\sum_n \lambda_n u_{n1}, u_{n2}, u_{nd}$ and its dagger, which is u_{n1}, u_{n2}, u_{nd} . And if we expand it, we can keep the sum over n outside and λ_n , it will be $u_{n1} u_{n1}, u_{n1} u_{n2}, u_{n1} u_{nd}, u_{n2} u_{n1}, u_{n2} u_{n2}, u_{n2} u_{nd}$ and so on. So, if we look at the ij th block of it, ij th block, we can write it as ij tensor the block and that block will be $\sum_n \lambda_n u_{ni} u_{nj}$ and sum over ij . So, this is the whole E prime matrix and E prime, if you remember its identity tensor ω acting on. Now, compare it with E and we will see that ω acting on ij is nothing but sum over $n \lambda_n u_{ni} u_{nj}$. And this thing can be written as sum over n since λ_n are positive numbers so we can define $u_{ni} \tilde{u}_{nj}$, where $u_{ni} \tilde{u}_{nj}$ is nothing but square root of $\lambda_n u_{ni}$ and if we define a matrix K_n such that the first column is u_{n1} , second is u_{n2} and we have u_{nd} . Then we can see that K_n acting on computational basis i will give us u_{ni} , so which means ω acting on ij can be written as $K_n \tilde{u}_{ij} K_n^\dagger$. Now, if we are given any operator ρ , we can always write it as ρ_{ij} , i outer product j sum over ij .

(Refer slide time: 32:40)

(Refer slide time: 34:20)

$$E = \sum_{ij} |i X j| \otimes \left(\sum_n d_n |u_n i X u_n j| \right)$$

$$\rho(|i X j|) = \left(\sum_n d_n |u_n i X u_n j| \right)$$

$$= \sum_n |u_n i X u_n j|$$

$$|u_n i\rangle = \sqrt{d_n} |u_n i\rangle$$

$$K_n = \left[|u_n i\rangle |u_n j\rangle \dots |u_n i\rangle \right]$$

There was sum over n also. Then omega acting on rho can be written as sum over ij rho ij omega ij and we have shown that omega ij can be written as K_n, sum over n, ij K_n dagger. We can take rho ij and summation over ij inside the summation over n, we get k_n sum over ij rho ij i outer product j K_n dagger and this is rho, so omega acting on rho can be written as sum over n K_n rho K_n dagger. Hence, proved.

(Refer slide time: 36:07)

$$K_n |i\rangle = |u_n i\rangle$$

$$\rho(|i X j|) = \sum_n K_n |i X j| K_n^\dagger$$

$$\rho = \sum_{ij} p_{ij} |i X j|$$

$$\rho(\rho) = \sum_{ij} p_{ij} \rho(|i X j|)$$

$$= \sum_{ij} p_{ij} \sum_n K_n |i X j| K_n^\dagger$$

$$= \sum_n K_n \left(\sum_{ij} p_{ij} |i X j| \right) K_n^\dagger$$

$$\Rightarrow \rho(\rho) = \sum_n K_n \rho K_n^\dagger$$
